In today's highly competitive marketplace, college students demand that education be of high quality, of reasonable cost, and with good support services. The evaluation of physical education quality has become a feature of the higher education landscape [1]. On the one hand, physical education quality assessments are being carried out by the new national funding bodies in response to the needs of society in the present age. On the other hand, the major stakeholders in higher education increasingly want to be assured of the quality of physical education.

In fact, the evaluation of education quality can be planned and implemented by small, i ndependent task groups. Heads of schools and evaluation departments have been encouraged to monitor the operation of their evaluation assessment schemes in order to improve educa tional quality. Much experience in the higher education system has led to the conclusion th at high quality is one of the keys to improve physical education [5].

The content of this article touches upon the construction of an evaluation index system for physical education quality. No attempt has been made to establish an absolute evaluatio n index system, because it is felt this would be not only impractical but also restrictive [6]. The present quality assessment systems for physical education can be conveniently used in developing a new system. The first step was to set up an evaluation index system involvi ng the formal appraisal of staff performance and the effectiveness of the education process. The second step was to set up a more effective evaluation model based on the analytic hi erarchy process (AHP) method. The evaluation index system for physical education quality i s extremely varied。

After the literature review, the author introduces a new model for administrative management to strengthen the existing evaluation index system. In this article, the author attempts to provide a finished model for physical education evaluation by using the AHP method. There are different qualitative and quantitative indicators for physical education quality. The aim of this study is to provide a tool to facilitate this. The effective assessment of the quality of physical education is one of the keys for education administrators in implementing university education.

Research discussed in this article is logically ordered into various sections. First, the eva luation index system for physical education quality based on the AHP method is presented. In the next section, the application of this evaluation index system is explained through a case study. Finally, conclusions are drawn.

Evaluation index system for physical education quality

In such a diverse environment, there are a number of methods that can be applied. In the study outlined in this article, an evaluation index system of physical education quality, based on an analytic hierarchy process model, was applied. A novel model is presented in this article for a college evaluation index system for physical education quality. The proposed model and its evaluation index system would enable a physical education quality evaluation.

The Ahp Method

The analytic hierarchy process or AHP method, which was established in 1977, is a popular way to solve multiple criteria decision problems. The AHP method provides a comprehensive structure by which to combine both quantitative and qualitative criteria in the decision-making process. Practice has proven that the method is easy, comprehensive and logical. Based on AHP, the factors involved in undergraduate education can be varied and a unified evaluation index system can be created.

In the AHP method, the problem is structured hierarchically in different levels. Any complex problem can be decomposed into several sub-problems using AHP, and hierarchical levels, where each level represents a set of criteria relative to each sub-problem. As AHP is a very powerful method by which to solve complex decision problems, it was selected as the major tool in this study. Next, the simulation methods are described in detail.

The AHP method is based on the use of pair-wise comparisons, which lead to the elab oration of a ratio scale. In the AHP method, multiplicative preference relations are called ju dgment matrices, and are adopted to express the decision makers' preferences. The pair-wise comparisons constitute square matrices, as shown in the matrix (1), the values of which ar e between 1/9 and 9.

$$\begin{bmatrix} 1 & x_{12} & \cdots & x_{1i} & \cdots & x_{1j} & \cdots & x_{1n} \\ 1/x_{12} & 1 & \cdots & x_{2i} & \cdots & x_{2j} & \cdots & x_{2n} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 1/x_{1i} & 1/x_{2i} & \cdots & 1 & \cdots & x_{ij} & \cdots & x_{in} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 1/x_{1j} & 1/x_{2j} & \cdots & 1/x_{ij} & \cdots & 1 & \cdots & x_{jn} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 1/x_{1n} & 1/x_{2n} & \cdots & 1/x_{in} & \cdots & 1/x_{jn} & \cdots & 1 \end{bmatrix} \quad (1)$$

As mentioned before, in this study, the AHP method was applied to evaluate the quality of physical education. The AHP method searches and evaluates the cause and effect relatio nship between a goal and alternatives by breaking down the structure of the problem. Finall y, the AHP method was used to measure education quality by utilizing the evaluation index system.

Proposed evaluation index system based on the ahp method

As the pace of market globalization quickens, the number of potential evaluation indices of physical education quality assessment increases; and the aim of this study was to develop an evaluation index system of physical education quality that would be effective and efficient. A large attribute set has been reduced and transformed into a lesser number of sub-targets to facilitate the evaluation of education quality.

This study introduced the AHP method to establish an integrated evaluation model. The physical quality education problem involves analyzing and measuring the performance of a s et of candidate indicators.

Case study of physical education quality evaluation

During the case study, the AHP method was applied to solve the problem of physical education quality evaluation. The proposed evaluation index was used by an independent college in China's Hubei province. The staff implemented a physical evaluation in their departments as part of a quality assurance process. It included a total of 17 criteria, divided into five cognate groups covering all the basic aspects of the college course. The evaluation index system of physical education quality is shown in Figure 1. The criteria were based on the overall aims and objectives of the physical course.

In the study, the AHP method was applied to screen indexes and the weight coefficients were defined. According to the proposed model, the estimation of an evaluation index system of physical education quality involves the following phases. First, an investigation was carried out of current physical education quality. Second, an analysis was made of the legitimacy of the evaluation index system. Third, the evaluation process was transformed into concrete operational procedures and standards. At the same time, the evaluation indexes to evaluate physical education quality were selected. However, when the data are collected, it will be necessary for respondents to determine the complicated network of the state-education relationships.

Table 1: Evaluation index system and index weights

First class index		Second class index	
Index name	Index weights	Index name	Index weights
A: Talent development	0.285	A_1: Course content	0.137
		A_2: Course proportion	0.284
		A_3: Course construction	0.193
		A_4: Textbook compilation	0.386
B: Teaching methods	0.207	B_1: Teaching approach	0.364
		B_2: Teaching means	0.245
		B_3: Teaching technique	0.391
C: Teaching staff	0.116	C_1: Construction and training	0.216
		C_2: Full-time teacher	0.183
		C_3: Scientific research	0.327
		C_4: Practical education	0.274

Thus, it was found that these proposals are not only very effective in helping AHP deci sion makers to reach consensus, but they also provide convincing alternatives for physical e ducation quality. Based on the findings from the preceding literature reviews, an AHP mode l was formulated to evaluate physical education quality, as shown in Table 1, the models o f AHP were studied, and the AHP algorithm was analyzed. Then, the AHP method was us ed to determine the weights of the evaluation index system for physical education quality. The basic information with respect to index weights is shown in Table 1.

Conclusions

The overall purpose of this article was to explore and contribute to an evaluative process for physical education quality. Automated evaluation makes the difficult task of evaluating physical education quality, simple and easy. The feedback received from the various institutions indicated that the evaluation index system has proved successful in achieving its various aims.

The evaluation results also provided a great deal of useful information about the effectiveness of the approved AHP model used in the education quality assessment process. At the same time, this work should prove its value as an empirical reference for other evaluation index systems for physical education quality for other nations or states. It is also hoped that it will be of interest to colleagues, and the author would be pleased to provide further information about the evaluation of physical education quality.

Experience and Enlightenment of American Internet Finance Supervision

Jianbo Hu

Guizhou University of Finance and Economics, Guiyang 550025, China

hjbbo@126.com

Keywords: Internet Finance; American Supervision Experience;Enlightenment

Abstract. Emerging internet finance is a general term that based on the internet and formation of financing activities.Internet finance promotes national economic development and at the same time also increases the instability of financial markets. The internet finane except with traditional financial risk types, also brings new risks, such as technical risk, special law and system risk,information security risk, etc. In our country, there are no special laws and supervision to regulate and govern on internet finance, and also have no special department plan and support its development.The United States's finance is more developed, and the internet finance concept is widely popular and traditional bank network degree is more perfect. Based on this, the experience of the internet finance development and supervision of USA,which will undoubtedly have important strategic significance and practical application value to promote the internet finance healthy and orderly development in China.

Introduction

As to the internet finance, at present the theoretical and practice cycles have not yet formed a widely accepted concept of authority. Xie P, Zou C W (2012) and other scholars believe that the internet finance refers to an emerging financial that relying on internet financial tools such as payment, big data, cloud computing, social networking and search engines to realize financing, payment and information intermediary business[1]. In essence, the internet finance is the combination of internet technology and financial function, relying on big data and cloud computing, forming an open and functional financial forms o and its service system on the internet platform, including but not limited to the financial organization system, financial market system, financial products and services system, financial consumer groups and internet financial regulatory framework which based on network platform. In the United States financial where finance is more developed, the concept of internet finance is widely popularized, the network degree of traditional bank is relatively perfect, using the experience of its regulation of the internet finance will undoubtedly has important strategic significance and practical application value to the healthy and orderly development of our country.

Internet finance development and regulation of the American experience

1)The practice of American network micro credit supervision.The United States bring network micro loans into securities regulatory perspective, focusing on market access and information disclosure. Firstly, the federal Securities and Exchange Commission (SEC) requires internet credit platform registered as securities brokers, identifying that vouchers sold by internet credit platform are securities; Secondly, it is the high cost of registering with the SEC that prevented other potential market participants. For example, the registration cost of network platform Lending loan Club is up to $4 million, so the British largest net credit platform Zopa gave up entering into the American market; thirdly, the SEC focused on the fact that whether the net credit platform discloses information according to requirement. Once appear funding risk, as long as the investors can prove there are omissions or errors of the key information in the prospectus, then the investors can recover

the loss through legal means; Fourthly, in addition to the SEC registration, net credit platform also needs to be registered in the corresponding state securities regulator. The requirement of state securities regulator is similar to the SEC, but some states added some related standards of personal finance to investors, including a minimum income, the upper limit of the securities investment proportion of assets, etc[2].

2)The practice of American P2P industry regulations.The main practices of the US to P2P industry specific regulation include: Firstly, the United States did not formulate special laws for P2P regulation, and mainly by looking for existing P2P related legal content, through which find useful regulatory measures; Secondly, it is subject to the state and federal dual control; Thirdly, the Securities and Exchange Commission (SEC) monitor P2P lending in the way of information disclosure, mainly through mandatory disclosure, anti-fraud and other related responsibility to protect lenders; Fourthly, although the federal trade commission is not regulators, but it can take enforcement actions to P2P lending company which is beyond the scope of its power and involved in debt-collection of the third party. That is to say, the federal trade commission have law enforcement responsibility for P2P lending; Fifth, strengthen protection and supervision to financial consumer rights and interests, and the Consumer Financial Protection Bureau(CFPB)that established after the crisis is responsible for protection and regulation of financial consumer rights and interests of the P2P platform [3]. The savings institutions operating P2P platform involves residents mortgage lending, private student education loan, and working loan, or in accordance with the "other consumer financial products and the large participants in the service market ", or as a service provider in some cases, the P2P platform needs to accept a consumer financial protection agency regulation (Huang Zheng, 2013).At the same time, the consumer financial protection bureau accepts consumer complaints on P2P platform, in order to protect the borrowers.

3)The practice of American third party payment regulation.On the third party payment regulation problems, the United States mainly adopts the following five aspects practices: one is In the identification of nature of institutions, that will treat the third party payment companies and other types of banking deposit institutions differently, and list it as a "currency services" in the concrete regulation, identifying it as general enterprise which only engaged in money transfer or money services business, not a real deposit institutions, and not need to apply for and obtain the general banking business license in the law; Two is manage and regulate monetary service agencies in the form of licensing, specifying the content of initial capital, the free flow of capital, investment scope limit, recording and reporting system, anti-money laundering, etc; Three is regarding retention money of the third-party payment platform as debt, which under the supervision of U.S. Federal Deposit Insurance Corporation (FDIC). Platform retention money need to be put in ginseng protect commercial bank interest-free account, and the capital insurance limit of each account is 100000 dollars; Four is that stipulate all monetary service agencies need to register on the Treasury's financial crimes enforcement network FinCEN, and should be maintained through related identification before opening; Five is that monetary services accept federal and state governments' two-stage control. States formulate regulatory standards and scope under the federal law, undertaking corresponding regulatory responsibilities [4].

4)The practice of American crowd funding regulation.On April 5, 2012, the United States went through the Jumpstart Our Business Act (JOBS Act), which allow small firms acquire equity capital through crowdfunding on the premise of meet the requirements of the securities laws and regulations, and the United States become the first country which really change the articles of association of the relevant regulation and make citizens freely participate in crowdfunding[3]. The JOBS Act released the raise equity financing, and made detailed provision in protecting the interests of the investors. One is that letting go of all the raise equity financing appropriately. The JOBS Act clarifies crowdfunding platforms satisfied the following conditions don't have to go to the federal securities and exchange commission (SEC) registered to conduct equity financing: agent registered

by the SEC acts as an intermediary; Who raise no more than $1 million every year through the network platform; Investors' annual income or net worth is less than $100000, and the total funds shall not be more than $2000, or 5% of the total income; more than $100000, 10% of its income is available for such investment, but up to $100000. The second is to protect the interests of the investors. The JOBS Act puts forward the corresponding requirements for borrowers and financing platform provided services, in order to protect the interests of the investors. For borrowers, the JOBS Act cleared about four requirements. That requires complete the file in the SEC , and disclose information to investors and intermediary institutions regulations; using advertising to promote the issue is not allowed; Limit how to raise compensation promotion; Borrowers must submit the annual report of enterprise operation and financial situation to the SEC and the investors[2].

5)The practice of American internet financial regulation.In view of American regulatory practice for internet fund (The American version Yu E bao PayPal), as the PayPal money market funds is an independent entity which is not affiliated with PayPal entities and operate independently, strictly operate according to the federal Securities and Exchange Commission (SEC) rules and subject to its daily supervision, and the money market funds did not reflect in PayPal balance sheets, therefore, the authorities take status quo and relatively prudent countermeasures and have not yet taken it as a new special legislation to regulate[2].

The enlightenment of American internet financial regulatory experience for our country

1)Legal and regulatory framework of perfecting internet financial regulation.Legal risk mainly embodied in the lack and blank of internet finance law, legal documents. China's regulation of financial laws and regulations of object mainly is the traditional financial sector, because it could not cover many aspects of the internet finance, still further can't fit unique characteristics of the internet finance, which is bound to cause a certain number of legal conflicts. Specialized legal and regulatory files is still a blank, for example there is no clear legal norms in detail on the aspects of internet financial market access standards, the legitimacy of the works, traders' identity authentication, the electronic contract and the effectiveness of electronic signature confirmation, etc. Internet users will face a lack of law and the risk of conflict of laws in the process of using the internet to provide or to enjoy the process of financial services, easily getting into the dispute of the legal blind area, this will not only increase the transaction costs but also affect the healthy development of the internet finance[3]. Based on this, the relevant functional departments of our country should formulate the internet financial related laws and regulations as soon as possible, to protect the internet financial healthy and orderly development of our country.

2)Information technology to improve the internet financial regulation.Technical risk is the common fault of the almost all internet business, mainly reflected in two aspects of operation risk and security risk[5]. Operation risk is the possibility of potential losses caused by system reliability, stability and safety of major defects, mainly comes from investors or improper operation of staff[3]. The security of the internet financial risk is caused by the system reliability, obvious defects of integrity, specific performance are that hackers illegally invade system to steal customer information and cause customer losses, or internet companies design, operate and maintain the internet platform of system improperly, leading to the phenomenon that customer information is stolen and customer rights and interests is damaged. Internet companies should, therefore, prevent the customer information and customer money being stolen and other security issues, by modifying or deleting service program, on the certain defects existed in computer facilities (hardware and software), compatibility, and malicious attacks from internal network and external network. At the same time, we should also develop advanced, independent intellectual property rights of information technology facilities (including hardware and software), improve the level of the key technology of the computer system and key equipment security defense capabilities [5].

3)The mechanism of improving the internet financial regulatory system.One is that the internet companies strengthen the construction of internal control system, for example, establishing internal control system of audit to prevent internal personnel violating compasses operation and stealing and selling customer information[5]; Two is that we should build up a "firewall" between the traditional finance the internet finance, gradually establishing grading warning mechanism of internet finance market, innovating digital and off-site regulatory means, to improve the effectiveness of the internet finance regulation; Three is to build up a joint supervision main body system which give priority to “one bank and three commissions” and give auxiliary to Ministry of Science and Technology, Ministry of Industry and Information Technology, Ministry of Commerce, and State Administration for Industry and Commerce, Administration of Taxation and other departments, to realize the comprehensive supervision of internet banking business; Four is to strengthen international regulatory cooperation, promoting the coordination of the multinational network financial risk events, promoting financial international internet governance mechanism[6].

4)Strengthening the education and protection of financial consumers.Firstly, we should attach great importance to the education of financial consumers and investors, strengthening the consciousness of risk prevention[2]; Secondly, clear regulation subject as soon as possible, make protection methods of internet financial consumers' rights and interests, make specific provision on internet financial transaction security, risk taking and responsibility Liability exemption, information disclosure, privacy and data protection[6];Three is to found a dedicated internet consumer financial protection agency, responsible for coordinating with the internet financial related service complaints and dispute resolution; Four is to make regulatory measures and corresponding punishment measures to protect the rights and interests of consumers to the maximum extent[7].

Influential factors of college students' mobile phone recycling behaviors

WANG You-ying[1, a], MA Bu-qing[2, b]

[1]SHU-UTS SILC Business School Shanghai University, Shanghai 201800, China

[a]chenyoudy@126.com, [b]seahorse@126.com

Keywords: telephone recycle; Theory of planned behavior; structural equation model; regression model.

Abstract. As China's rapid development in economy and technology, people's consumption concept transforms fast. Thus, the mobile phone replacement cycle becomes shorter and shorter. Recycling wasted mobile phone is beneficial to reuse of resource and decline in environmental pollution. Researches show that, college students, whose consumption concept is between adult and teenager, have both rational and irrational behavior trend and have largest probability of changing mobile phones. This article analyzes characteristics of college students' recycling behavior and its influencing factors. Then, relevant suggestions are provided to enhance recycling efficiency.

1. Introduction

As the development of economy and the improvement of people's life standard, demand for electronic products increases. According to **s**tatistics from Ministry of Information Industry, users of mobile phones in China reached to one billion at the end of 2012 [1]. It has also been found, the number of annual wasted telephone has risen to over 5 thousands, which keeps increasing at the rate of 20% [2]. However, the current situation of mobile phone recycling is not optimistic in China. According to Nokia's survey report in 13 countries, the recycling rate in China is rarely 1%, which is far below than western countries. Researches show that college students are most activist users who change mobile phones. Therefore, based on the situation of mobile phone recycling, this article will study college students' features in recycling behavior, related influential factors and related mechanism. And then some improvement advices for recycling will be provided.

2. Literature Review

Some researchers have classified the recycling modes and treatment methods of mobile phone in China. Xia and Wang [3] found that wasted mobile phones were often given away to others or standing idle or selling to recyclers. Some useless parts of mobile phone were abandoned directly. Mu and Yang [4] considered the recycling process based on Life Cycle Analysis (LCA) of technical product, and concluded that the recycling mode of mobile phone in China was marquise-shaped. The causes of problems can be summarized as follow. Firstly, consumers usually have low awareness of recycling. Secondly, normal and effective recycling channels have not been established yet. Thirdly, the procedures and policies to motivate the manufactures are absent [5-7]. To address this issue, researchers have designed various recycling system for China's mobile phone market. Sun [8] came up with a reconstruction model after studying some factors about products, e.g., cost, quantity and price. Ma [9] also designed a model to describe industry chain of reconstruction system for wasted electronic products. Some scholars put forwards Extended Producer Responsibility based on experiences of western countries. However, there are few researches that pay attention to consumers' recycling behavior.

3. Questionnaires

A. Research Design

In order to explore customers' attitude and behavior tendency towards recycling, the questionnaire based on Theory of Planned Behavior (TPB) is divided into three sections. First part considers demographic factors, such as age, revenue, gender and education level. Second section contains

rational components, such as recycling awareness, attitude, and cost, etc. Third part has included some irrational factors like affection. Reading published articles is the main method to find basic factors, while interviewing and expert-consulting are used in probing affection factors.

After collecting factors, a small program named implicit association test (IAT) is operated to verify accuracy, in case that the process of probing influential factors would have errors. Until all factors have been tested, the questionnaire designing completes. Finally, the researched factors (i.e., independent variables) are attitude (A), subjective norm (SN), cognitive behavioral control (CBC), personal affection (PA), safety, past experience (PE), behavioral cost (BC), self-awareness (SA), orthodox recycle channel (ORC) , recycling awareness (RA) and bandwagon effect (BE). SPSS is the data processing tool used in this article.

B. Data Resource

As Shanghai is a prosperous metropolis where living standard is at the top of China and has higher possibility to suffer huge amount of wasting telephones, this article chooses some typical universities in Shanghai as the main data sources. Colleges in other provinces (e.g., Anhui, Jiangsu) are also considered. Then, unvalued data is removed to ensure data quality. Overall, the sample contains 94 females and 100 males, ranging from freshman to second grade of graduate students. 45% of them are Economy Management students, and nearly 25% of them come from Shanghai.

4. Data Analysis

A. Describing and Deducing of Independent Variables

Structural equation modeling (SEM) is introduced to classify questions and match them with independent variables reasonably. According to result of confirmatory test, comparison of goodness of fit index (CFI) has reached to 0.919, which gets close to 1. Therefore, the match model between questions and independent variables should be received.

After initially analyzing the researched data, it can be found that 42.6% of female and 55% of male who have changed mobile phones at least once. The main reason is the failure of the old telephone. Based on TPB, other descriptive statistics are conducted. In terms of attitude, 56.9% of participants believe that it is worthwhile to recycle wasted telephones and 56.4% of them are worrying about pollution caused by wasting. As for subjective norms, 53.8% of them will recycle if recycling has become a good social atmosphere. When it comes to behavioral cost, 64.8% of colleges will participate in recycling if the recycling process is standardized enough.

B. Analysis of Dependent Variables

1) Descriptive Analysis of Dependent Variables

According to statistics, there are mainly six disposing channels for wasted mobile phones. SPSS is used to calculate the percentage of male and female participants who choose each dissolving method. The results are shown in table 1. The two main treatments are standing idle (80.5%) and giving to others (14.9%). Furthermore, two genders also behave differently in choosing disposing methods. In detail, male prefers these three options: to stand telephone idle, to give others and second-hand sale; however, female often choose to stand idle, to give away and to throw away.

TABLE1 Percentage of Current Disposing Methods for Wasted Mobile Phone

		Recycling site	Sell to waste collection	Give to others	Throw away	Second-hand sale	Stand idle	Total
women	Amount	1	1	16	6	4	79	95
	% in women	1.1%	1.1%	16.8%	6.3%	4.2%	83.2%	
	% in men and women	50.0%	50.0%	55.2%	50.0%	36.4%	50.3%	
	% in Total	0.5%	0.5%	8.2%	3.1%	2.1%	40.5%	48.7%
men	Amount	1	1	13	6	7	78	100
	% in men	1.0%	1.0%	13.0%	6.0%	7.0%	78.0%	
	% in men and women	50.0%	50.0%	44.8%	50.0%	63.6%	49.7%	
	% in Total	0.5%	0.5%	6.7%	3.1%	3.6%	40.0%	51.3%
Total	Amount	2	2	29	12	11	157	195
	% in Total	1.0%	1.0%	14.9%	6.2%	5.6%	80.5%	100.0%

2) Difference Test of Dependent Variables

In order to estimate whether there is any difference between above disposing methods, based on data from sample, percentage U Test is applied. Take throwing away and second-hand sale as an example, if p_1 and p_2 represent percentage of people who respectively choose to throw away and choose second-hand sale, then

(1) Give null hypothesis and alternative hypothesis:

H_0: $p_1=p_2$; H_1: $p_1 \neq p_2$

(2) Calculate the value of u and uc, the equations are as follow:

$u= (p_1-p_2)/S_{p1-p2}$, $u_c = (|p_1-p_2|-0.5/n_1-0.5/n_2)/ S_{p1-p2}$,

$S_{p1-p2} = [p' (1-p') (1/n_1 + 1/n_2)]^{1/2}$, $P' = (n_1*p_1 +n_2*p_2)/ (n_1+n_2)$

After calculating, the absolute value of u or u_c will be compared with 1.96 and 2.58, only under the circumstance that |u| is less than 1.96 can null hypothesis (H_0) be received. Here, because u is 10.94 (> 1.96), it can be concluded that there is a significant difference between various recycling alternatives, on the premise of 5% significance level.

C. Regression Analysis of Variables

In order to reduce the subject errors caused by deducing independent variables from reading published articles, correlation analysis of independent variables is conducted. Table 2 presents that, there is strong correlation between behavioral cost and orthodox recycle channel, bandwagon effect and subjective. Furthermore, recycle awareness is tightly related to cognitive behavioral control and personal affection. It also shows that personal awareness and bandwagon effect have high correlation with each other.

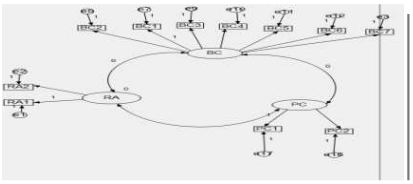
*at the level of 95% significance

**at the level of 99% significance

To merge independent variables that have high correlation with one another and to simplify variables, we calculate and compare the value of CFI to create the fittest model. The process completes until each variable has low or no correlation with each other while the value of CFI is still high. After that, another correlation analysis will be conducted using independent variables being merged. The details are shown in Fig.1, and BC, RA and PC stand for behavioral cost, recycling attitude and personal affection, respectively. The CFI value of modified model (0.921) is larger than that of original model (0.919), which proves the modified one has higher accuracy. Eventually, above seven variables (will be regarded as regression variables.



Baseline Comparisons

Model	NFI Delta1	RFI rho1	IFI Delta2	TLI rho2	CFI
Default model	.860	.825	.922	.901	.921
Saturated model	1.000		1.000		1.000
Independence model	.000	.000	.000	.000	.000

Fig. 1 Modified and Tested structual equation model

1) Regression Model

This part focuses on establishing regression models and equations to numerically describe the relationship between dependent and independent variables. Take standing idle as an example, after SPSS standardizes the data, regression analysis reveals a regression equation (1) about dependent variables (standing idle) and seven independent variables:

$$Y_1 = -0.204 * X_4 - 0.147 * X_5 \quad (1)$$

In (1), X4 and X5 respectively stand for standardized value of past experience and cognitive behavioral control. It can be deduced that higher value of cognitive behavioral control and past experience of recycling will lead to less possibility to stand wasted telephone idle. The procedures of regression analysis about other dependent variables are similar to above-mentioned process, other dependent variables and relative main influential factors are listed in table 3.

TABLE3 Recycling Behavior and Major Influential Factors

Recycling behavior	Throw as rubbish			recycle	Giving to others	
Main influential factor	Cognitive behavioral control	Behavioral cost	Subjective norm	Behavioral cost	Cognitive behavioral control	Self-awareness

For the purpose of improving exploring accuracy, based on results of simple regression analysis, square data prediction is conducted. In detail, for each disposing option of wasted mobile phone, we calculate square of excluded variables and deal with regression analysis again. Table 4 shows the relationship between disposing decisions and square of factors. According to it, although both option of standing idle and throwing away are closely related to personal affection, they have positive and negative relationship with personal affection factor respectively.

TABLE 4 Quadratics Equation of Recycling Behavior and Factors

Options of disposing methods	Standing idle	Throwing away	Recycling
Quadratics factors	Personal affection	Personal affection	Subjective norm

4. Conclusions and Advices

This article briefly describes recycling situation of mobile phone and analyzes related problems and causes. Then based on Theory of Planned Behavior (TPB) and Implicit Association Test (IAT), a survey is applied to collect data about mobile phone users. According to analysis results, different recycling methods are decided by different factors. The option of standing idle is related to past experience, cognitive behavioral control and personal affection. The behavior of giving away to others is decided by cognitive behavioral control and personal awareness. The option of throw away is linearly dependent on cognitive behavioral control, behavioral cost and subjective norm, while has binary linear relation with personal affection. The behavior of recycling mobile phone is linearly related to behavioral cost, but has binary linear relation with subjective norm.

Some advice is put forward to improve recycling rate. Firstly, more attention should be paid to recycling convenience for users. Secondly, normal and professional recycling pricing system should be established. Thirdly, more announcements and education about benefits of recycling should be conducted among users. Last but not least, the information security of users when participating in recycling must be protected. The survey in this article still has some limitations in questionnaire designing and sampling, it is worth expecting richer researches to emerge in future.

Keywords: Teamwork; Project Teaching; Role Orientation; Contribution Rate

Abstract: At present, students' education is still in an independent, passive and closed learning environment in university: students still passively accept knowledge and study what teachers teach, that leads to a state that the study is passive and closed. Therefore, teachers should guide students to emphasis on teamwork and overall, active and open teaching, to attach importance to team work, to actively explore the issue and try to apply a variety of ways and resources both within and outside the school to solve the problem, not confine to knowledge in textbooks.

1. Preface

At present, university education in our country is still in the state of training the students' ability to solve problems, in stead of cultivating the students' ability of problem mining, solving, and then creating. This is our country long-term formed disadvantage under the entrance examination system for many years. Once students leave school, go out of the classroom, go into the community and go into the enterprises, they are lack of the adaptability and future creativity.

This teaching method used in programming courses has been implemented for three years. Under this teaching method, students can completely study themselves and experience the mode of operation in the simulated real environment after leaving school and then don't have any regrets for the disconnection between theory and reality. Of course, whether this teaching method can be integrated into other disciplines has been required to further verify.

2. Teamwork

2.1 Team size

5-7 students per team (this can be adjusted according to the number of students in the class).

2.2 Role orientation (the duties and powers: according to the nature of curriculum, teachers can consider role types by themselves)

(1) Project Manager (1 student)

He must co-ordinate the overall situation, be responsible for the team project planning, the project schedule control and so on; he is the team's supreme executive and has the exercise right and the right to a veto vote, etc.

(2) Systems Analysts, System Architects (1-2 students)

They are responsible for client interface, acquiring requirements, selecting the development process, tools and methods, global system architecture design and so on.

(3) Database Engineer (1 student)

He is responsible for system data format specification, the choice of data persistence method, design of data access class and so on.

(4) Software Designer, Test Engineer (1-2 students)

They are responsible for the design and coding of software module, perform unit testing, integration testing, system testing, and organizing clients to conduct validation testing and so on, then finally complete the system implementation.

(5) System Artist (1 student)

He is responsible for image design of system identification, human-computer interface and so on.

2.3 The team culture logo

Each team must design identification and culture concept.

2.4 Team meeting

Each team must have regular team meetings, build up the common vision, draw up the team planning, arrange team task of the near future, talk about team work plan, in order to exercise debate eloquence, learn communication skills, and gather more team centripetal force.

3. Project Teaching

In order to improve the teaching schedule of program design course, cut the grammar explanation time, increase the intensity of work development explained, this teaching method is based on project teaching method and looks for software development case to explain, to improve the students' level of software development, and expand the students' knowledge.

4. Team division

The first wrong solution: only establishing outstanding students' team

Once leading to the consequences: maximum potential for outstanding students will give up most of the students as the sacrifice. Most of the students lose interest in learning the course, and it is easy to let the students have a sense of inferiority (they feel not as good as the outstanding students), jealousy (students can easily be leaded to estrangement), and this is not conducive to the harmonious of class collective.

The second wrong solution: allowing students to set up team freely

Once leading to the consequences: outstanding students freely combine themselves into only one team, so that the teams' competition is not fair, the teams' rankings has been established without no assessment and this solution is not competitive.

The third defective solution: establishing the team through the teacher and class representative's participation.

Once leading to the defect: higher vocational students' foundation is generally too low, with high level, high understanding students in a minority. Most students have great dependence, inert because of the boring program design and teamwork cannot get sufficient play. With few members working, project progress is slow and most developed works seem to be some insufficiency, lower-tech because of limited manpower and knowledge limitations.

The fourth optimized solution: based on the third solution, we will set up a teaching assistant team alone (outstanding students in each team) that will carry out the following work:

(1) For the teaching assistant team, teacher will train them to master the basic knowledge and basic skills after school or computer-experiment, then these small sirs shall provide guidance to team members and let the students master the knowledge and the practical skills through classroom randomly testing ways (test scores are included in team scores).

(2) For the teaching assistant team, teacher will train them to master the advanced knowledge and extended skills after school or computer-experiment. They will be composed of technological development team to develop the big projects, so as to realize the focused training of top students.

5. Testing ways

So-called "no pressure, no power", closed education only is unreasonable, and opening education simply is not practical. When the education is only paid attention to the form and is forgotten its purpose, this will become a misunderstanding. We always say students' burden. If we

cut the length of the school hours, reduce the difficulty of the course examination, reduce the pressure of studying, what will happen? Some students have entered the game room, cinema, played cards, chatted on QQ, picked up internet addiction and it has interfered with the normal school education. Opening education is not a liberal education. If the school gives students opening education with free style, the students will relax to own request. That is because now college students' self-control ability has not yet reached the degree of conscious learning without a reminder. So adopting various testing ways which make the students highly focused, such as quizzes, homework or training report, mid-term exam or research report, attendance, curriculum design and the final exam, will let more students feel learn something.

6. The role orientation between teachers and students

At the end of the semester, the works published will be raised. At the scene simulation product launch, all students can perform on the stage according to their own role in the team, setting up the assessment group, carrying out the comments and letting the audience of students speak freely, in order to exercise the stage students' eloquence of the debate, expanding the audience students' vision and knowledge.

At the moment, teacher is a listener, an adviser and an inspirator. Students become very easy to communicate with each other, because they consider it is their work and responsibility. The classroom is not only the classroom bus also has been transformed into a performing venue. This adjustment of the team learning and the roles of teachers and students is a rare experience and enjoy for us who are accustomed to the traditional roles of teachers and students.

7. The contribution rate

In team learning, in order to inspire students to unite in a concerted effort, go to all lengths, to avoid the previous too strong dependence and inertia of some members of the team, and to avoid the regret for the unfair results of each team member's with same score, teachers should prearrange on the score calculation. The basic practice is: at the end of the semester, each member in the same team will be separated to check and evaluate each other in secret. the rating method is that Si Li, Wu Wang, Liu Zhao will be evaluated by San Zhang, the total score is three hundred points; in the same way, the others will be evaluated by Si Li, and then each team member's scores will be added up by teachers after class; the scores will be divided by 300 and the contribution rate will be worked out. As in the example, San Zhang gets 110%, Si Li gets 86.7%. The rating data shall be kept by the teachers for a period of time, in order to prepare students for asking for review.

Table 1 The calculation example of contribution rate

Name	Score 1	Score 2	Score 3	Score 4	Total
San Zhang		100	120	110	330
Si Li	90		80	90	260
Wu Wang	110	100		100	310
Liu Zhao	100	100	100		300

San Zhang's contribution rate：330/300=110%

Si Li's contribution rate：260/300=86.7%

8. The score conversion

Using the team PK (competition) mode in order to improve the practicability of this mode. The score conversion method is as follows:

- 5-7 students per team (this can be adjusted according to the number of students in the class).
- The team PK scores= Quizzes (20%) + Curriculum design (80%).
- Calculating every member's contribution rate by the way of grading each other in the same team.

- Personal PK scores=team PK scores*personal contribution rate.
- Personal final scores= Homework scores (10%) + midterm exam scores (20%) + attendance scores (10%) + personal PK scores (60%)

The reason why the author doesn't put homework scores, midterm exam scores and attendance scores into the team PK scores is in order to avoid the too many dependence and inertia of some members of the team and avoid the entire team scores being very low because of someone's poor scores

9. Summary

Above all, you can understand the design conception, the principle, and the implementation process of the teaching method. This teaching mode has cultivated students' sense of teamwork through certain team cooperation, has improved students' practical ability, has made the students take the initiative to study spontaneously, has made the students enjoy the classroom performance like competition of places, has letted the education go out of the classroom, into the community, into the enterprises and has provised a good platform for practice to make students quickly adapt to the job and get into work units.

Keywords: international river；information integration；integrated development and management.

Abstract: Integrated development and management of international rivers requires objectively international river's information integration.Based on the analysis of the connotation and requirement of integrated development and management of international rivers, the article point out that the information integration is the basis and means of the of integrated development and management of international rivers. And then analyze how to utilize modern information technology to build information management system of international river to achieve international river's information sharing and scientific decision-making. Finally, analyze the factors affecting international river information integration.

0 Introduction

International rivers have the features of water body flowing, integrity of hydrology and geography and being politically divided into different parts and belong to different countries, which made basin countries influence and interdepend each other in exploiting and utilizing the international rivers. And the ecological and environmental problem caused by exploiting and utilizing international rivers will spread to the whole basin countries. All above increase the possibility of conflicts and disputes among or between watershed countries for exploiting and utilizing international rivers which seriously threaten to the regional peace and stability and the security of water resource. Since 1990s, along with the development and infiltration of the concept of sustainable development and the idea of integrated river basin management, the theory of integrated development and management of international rivers began to formed and initially piloted in a number of rivers. The theory emphasizes the integrity of the system and the relevance of the elements of the international rivers and requires to implement integrated multi-objective overall watershed planning and water resource management. The theory also require embodying protection in the planning and to realize protection during exploiting and utilizing the international rivers, in order to ensure the regional security and stability of international society and the sustainable utilization of water resources.

Integrated development and management of international river basin is built on information integration of international rivers. Information integration of the international river can help to achieve information sharing among the river basin countries and enhance their mutual understanding and trust, and make decision-making based on scientific and fair basis, which can promote a large process of the integrated development and management of international rivers.

1 The Theoretical Connotation of Integrated Development and Management of International Rivers Require Objectively the Information Integration of International Rivers

The theory of integrated development and management of international Rivers which is based on system theory, sustainable development theory and the coastal community of interests theory, during the 20 years of development of theory and practice, has formed the following connotation and requirements:

(1) Because of system wholeness and regional linkage of international river basin, development and management of international rivers requires cooperation between or among basin countries. International river basin boundary and the boundaries of countries are not consistent, but itself is a system.There is inevitable connection between regions in basin and between upstream and downstream counties.So a single country cannot resolve problems such as soil erosion, salinization, river cleaning,water wasting, pollution and

other cross-border issues. Because the interests and goals of different countries in developing and using water resource are disaccord, it is easy to cause the contradiction and conflict. For example, the upstream countries' irrigation utilizing and hydropower development will decrease water level of downstream and bring affect to downstream ecology, so downstream countries is bound to oppose. Therefore they are objective requirements to look the international river basin as a whole, strengthen the cooperation between riparian countries, coordinate with each other in the target of using, compensation benefits, to reduce conflict.

(2)The relevance between the various elements within the catchment basin require overall planning and coordinated development in basin. The development and utilization of any resource should consider the effect to other related resources. Land using (such as cropping, grazing, deforestation, road construction, mining, urbanization, etc.) usually cause a series of changes in the water quantity and water quality (such as runoff, runoff velocity and sediment), and cause generation, migration and transformation of pollutants through water. In addition, the basin's land planning and layout of the economy and social culture all exert important effect on the spatial and temporal distribution of water resources and water environment and ecology. Therefore, the international river resource management cannot be separated from other resource management and must conduct a overall planning and integrated management.

(3)The coastal states' relationship of the interests of the community requires joint management. As a geographical and economic unit, international river basin is the community of interests, just like that all basin countries take "a leakage world boat", because ecology, water quality problems are related to the survival of all river basin countries. So they should share resources and share the future. The integrated management is the direction of development. Basin countries jointly established watershed management international institutions to formulate and implement of integrated river basin management and development policies and to achieve the best overall development objectives and the entire watershed.

(4)The scientific and openness of decision-making of integrated development and management requires information sharing and joint participation requirements. The development of international river is changing from separate development of a single country to joint development of basin countries. Participants in international river development include not only very basin country but also non-governmental organizations, associations, private investors and etc. Developing programs and policies that multiple subjects involve in must base on comprehensive and objective information sharing basis ,to ensure decision-making scientific and acceptability.

The theoretical connotation of integrated development and management of international rivers require objectively the information integration of international rivers. First,international rivers' basic geographic and hydrological information should be integrated.For a long time,basin countries of many international rivers lack of the basic informational exchange platform due to geographical, linguistic, political barrier, resulting the basic data of international river deficient and lack of uniform standards. Joint research results based on watershed overall is little, which hindered basin countries to cooperate on the integrated development and management of international river. Furthermore,consensus and common decision-making of the integrated development and management of international river must be based on information sharing, strengthening mutual understanding and trust, in which the information integration play a key role.Finally, the water resources development, utilization, management, configuration,flood control and disaster mitigation, water conservancy construction and benefit distribution cannot do without the support of modern information technology. Therefore the international river information integration is the foundation of the integrated development and management of international rivers, only to achieve information integration to promote the implementation of integrated development and management of international rivers.

International river information integration is to build a integrated information system platform between watershed countries, through which it can achieve integrated management of international river basin information data collection, processing, storage, analysis,simulation, and the output. Aim of doing this is to achieve watershed information sharing and to form consensus and scientific decision of the integrated development and management of international river. Therefore, the river information integration is not objective,but the means to implement integrated development and management of international rivers.

2 The Way to Information Integration of International River—Constructing Jointly the Integrated Information Management System of International River Using Modern Information Technology

2.1 A Brief Introduction of Modern information technology

Modern information technology is combined of computer technology and electronic communication technology which both are based on microelectronics. And it is a general term of the technology of acquisition, processing, handling, storage, dissemination and using information such as voice, image, text, numbers and various sensing signals. The core of modern information technology is the information science. Modern information technology is a very extensive technology group,which includes micro electronics technology,electronic technology, communication technology, network technology, sensor technology, control technology and display technology. Enter in 21th century, the modern information technology is rapidly developing as the speed that other technologies never have and is involving in all aspects of society in the depth and breadth that other technologies never have. Especially with the development, mixing and integration of three space technology- remote sensing (RS), global positioning system (GPS)and geographical information system(GIS)and modern communication technology,especially wireless communication technology ,a strong technology system has formed, which can realize to collect, process and update the spatial information and environmental information rapidly, flexibly ,accurately and reliably. Modern information technology shows a broad application prospect,especially the "3S" technology has been widely used in city planning, land use, investigation and management of resources, ecological investigation of watershed planning and management, and recovery, environmental monitoring and protection, disaster prevention and mitigation.

2.2 The application of modern information technology in the integrated information management system of international river

The construction of the integrated information management system of international river, which based on the integrated development and management, aims at building a technology system through application modern information technology, which can realize collection, management, operation, analysis, simulation, display and output of international river basin spatial, non spatial data (text, digital).Through the information transmission and sharing, the system can achieve a comprehensive, accurate, timely grasp of the information of international river, it can help to made the international river basin planning,allocation of water resources,ecological environment management and project construction on the basis of the jointly and scientific decision.The integrated joint decision of the basin countries based the information sharing can enhance the cooperation of the riparian countries and benefit sharing, realize the principles of international law of fair and reasonable utilization of international rivers and not causing significant damage, reduce the disputes and conflicts in the development and utilization and the ecological environment protection of international rivers .

In order to realize the system functions, the integrated information management system based on the integrated development and management of international river is made fo three subsystems which Closely contact with each other and support each other.

(1) Data acquisition subsystem.Data acquisition subsystem is mainly distributed in the river basin management agency of basin member countries of international river,which are responsible for collecting and providing the relevant basic information of the domestic part of international river basins,including hydrology, water quality,biology,land use, the quantity of water using,sewage, the forest coverage, soil erosion,meteorological phenomena and so on, which relates to all aspects and are updated.The technologies used are mainly 3S technologies in addition to the environmental monitoring equipment, on-site investigation and other traditional methods.

(2) Information integration, processing, management and maintenance center system.The system is the key part of information system of the integrated development and management of international river basin. It has two functions.The one is classification , numbering, saving, adding and updating to the information in the data library that is ready at any time to be called by each application subsystem.The two is information processing,analysis and summary, generating charts and at last forms watershed integrated information,such as the total annual flow,sediment,Biological community distribution,pollution discharge,the rate of pollution

discharge,etc.This system provide information and data for decisions of international river water resource basin planning,allocation,Comprehensive development and utilization,ecological and environmental protection and management.And it is the foundation to solve international disputes on water.

(3) Application of decision subsystem.The subsystem is the system to realize the aim of the integrated development and management of international river basin information system,which apply the information and data to the specific decision of development and utilization, protection and management of international river to ensure decision-making being scientific. The subsystem can provide support for decision-making through constructing various mathematical models that have forecasting,analysis,simulation and evaluation function.For example, the water distribution and scheduling model, hydrology stimulation model,river eco-environmental water requirement water model, conservancy and hydropower project environmental impact assessment model, watershed ecological planning model, flood disaster prediction and flood control decision model,etc. The main technology applied in this subsystem is computer information processing technology.

The structure of the international river integrated information management system based on the integrated development and management of international rivers see Figure 1:

2.3 Information Sharing and Security Control

The information collection subsystem that distribute in every basin member countries and the information integration,processing, management and maintenance center system and the application of decision subsystem achieve the interconnection and resource sharing through internet technologies.The information center of Comprehensive Management and Coordination Committee of the international rivers is central platform of information connected which provides the unified software and hardware environment for development and operation of each subsystem and complete the information collection and transmission.

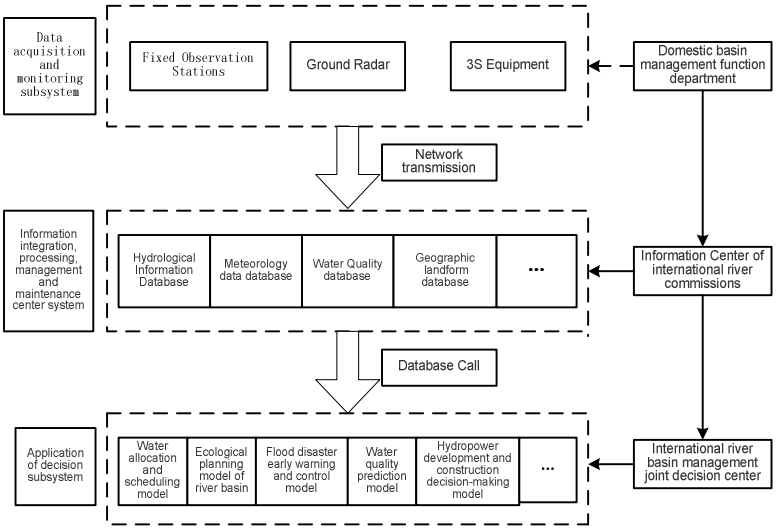

Figure1 The structure of the international river integrated information management system based on the integrated development and management of international rivers

In addition, the system can set the public information platform that realize the connection through the network and external network,let basin public participate and understand of international river's information and development and management decision-making , protect the public's right to know and participate.

The information of integrated development and management information system of international river may involve state secrets that is at stake sovereignty security and political stability.In order to ensure the information security, it is necessary to control of information system security. Applying authorization management of the access to and use of database and encryption technology,the system can prevent the information leak to unauthorized individuals or entities,and protect information are not modified, damaged and lost in exchanging, transmission, storage and processing, keep information intact and complete.

3 The Analysis of Factors that Influence on International River Information Integration Advancement and Implementation

Information integration is the basis and means for promoting the integrated development and management of international river.In turn, the degree of the impact and acceptance of the idea of integrated development and management of international river will also affect the promotion and implementation of information integration of international rivers.The two complement each other.Because the international river problems relate to water resources sovereignty of different countries and and are affected by complex geopolitical and economic factors,to promote and implement the international river information integration in a international river basin will be influenced by mang factors.

(1)The political will of cooperation of the integrated development and management of international river

The integrated development and management of international river emphasis the overall interest of basin.When the overall interests of the basin conflict with national self-interests and difficult to co-ordinate, if basin countries are unwilling cooperated and take unilateral development and management,the integrated development and management of international rivers would be difficult to implement.In this case the basin countries will not support the information integration of international river basin. At the same time, based on political mistrust, the watershed countries are not willing to share information, and even to protect information of international rivers as state secrets.

(2)Regional cooperation system and mechanism.

The political, economic, technological, cultural exchanges and cooperation between countries of the region,including the system and mechanism of cooperation, can strengthen their relation of mutual trust and mutual dependence, which can create positive and effective conditions for the establishment and development of the mode of the integrated development and management of international river. The higher the degree of international regional economic integration, information exchange and sharing of between countries will strengthen.So it will be easy to promote the implement of the integrated development and management of international river.The development of the North American Free Trade Area and the European integration has played an important role in promoting integrated management of international river basin,in which information integration plays an important role.

(3) Organization guarantee of International river information integration.

In recent years, with the deepening of the international river basin integrated management idea,it has become a trend for coastal states to establish international river joint management organization according to the agreement or treaty to coordinate the international river development and management.Many international rivers have established a similar international river commission.Management of international river information integration function should become one of the important functions of International River Commission, responsible for the operation of integrated information management system of international river, coordinate the domestic river basin management agencies or departments, to promote the construction of river information integration.Domestic river basin management agencies and departments of is specifical department involved in information management, including the collection and provide real-time hydrological, geographical, river water quality dynamic information, to participate in international river agreement negotiation and decision process.

(4)Talent and funds to support the information integration of international rivers.

The construction of the international river information integration needs the support of capital. On the one hand for the purchase of equipment, software development, Internet information maintenance and other costs, on the other hand for the funds of the introduction of the talent and research expenses. Operation and management of international river information system need numerous and technical experts and jurists to

bend themselves into the information system development, maintenance,management, and use the information to carry out applied research, making integrated development and management scheme, rules and communication and coordination, participation in contract negotiations and settling disputes and disputes.

4 Conclusion

With the development of the crisis of the world's water resource, the problems of the development and utilization and income distribution and environmental and ecological protection of international rivers water resource become the focus of regional conflicts. The integrated Development and management model of international river is the right development direction to solve the conflicts between protection and utilization of international rivers,which has put into practice in the economically developed regions in Europe and America.International river development and management based on the information integration of international rivers and rely on information integration implementation. Using the modern information technology to construct the information system of the integrated development and management of international rivers, will greatly promote implement of the integrated development and management in international river basins, and realize the balanced and sustainable development of the economic developing, social justice and ecological protection in the international river basin.

Keywords: Planning and site selection, functional zoning, indicator system, Analytic Hierarchy Process, Panzhihua City

Abstract. In order to standardize the patterns of land use for urban infrastructure construction, and improve the scientific and rational nature of site selection for urban infrastructures, a method of site selection and function zoning for urban infrastructures, which is oriented to the main function zones, is proposed. Based on the planning concept of main function zones, the indicator system for site selection and function zoning is established according to the conditions of areas for site selection, and the areas for site selection and function zoning for urban infrastructures are divided into various function zones. The practical application with Panzhihua City as an example indicates that the main function zones-oriented method of site selection and function zoning for urban infrastructures both embodies and takes into account the radiation of urban infrastructure functions, and rationalizes the layout of site selection for infrastructures and also optimizes the urban spatial pattern. The proposal and application of this method provides guidance on the decision-making for urban infrastructure planning.

Introduction

Site of urban infrastructure planning area is an important part of city infrastructure planning. With the continuous progress of urbanization, urban infrastructure problems caused by unreasonable siting become increasingly prominent, mainly in waste of resources caused by blind siting a lot of land, irrational facilities lead to duplication facility or facilities in short supply, and environmental damage caused by ignorance impact of facilities on the environment[1-2]. In order to improve the scientific nature and rationality of facility location, some cities plan site suitability evaluation. in facility location. Suitability assessment for a single project site you improve facilities siting unreasonable conditions, but due to lack of macro-regulation and co-ordination on the site of space, facility location still has arbitrary, and is not conducive to the conservation and space pattern optimization of land resources.In view of this, we propose a method of urban infrastructure site planning oriented MFOZ. Based on division thinking of the main functional areas, urban infrastructure siting space is divided into different functional areas due to the location of regional conditions, to improve urban infrastructure siting science and rationality,optimize urban spatial structure, and improve land utilization.

The principle of the main functional area planning method

The main functional area planning is a macro planning methods to optimize the spatial structure, mainly used in large space planning such as country, province, city etc. The main idea is based on different regional conditions, considering population distribution, economic layout, land use and urbanization patterns, identifying the main functions of different regions and a clear development direction, controlling the strength of development, and regulating the development order [3-4]. City Infrastructure Planning Division is also partition of large scale regional land space. Based on regional

environmental characteristics , optimize the allocation of resources through function, rational space layout of city infrastructure, improve the scientific planning, reduce the ecological environment destruction of the blindness location. In this paper, by learning from the district planning methods of main function, define facilities planning area for different functional areas, combined with the city basic facilities location conditions, construct facilities location function area dividing index system to realize the function division. Take Panzhihua City, Sichuan Province as an example, to prove the division of functional areas location of city facilities based on the of main functional area planning.

The location area planning method

Facility location function classification. In this paper, reference to define and classify of the main functional areas, combined the characteristics and requirements of urban infrastructure planning siting , considering various towns in Panzhihua City as planning unit, the infrastructure planning siting area is divided into key planning areas, encouraged planning area, and restricted planning area three types of functional areas. Among them, the key planning areas means the area whose infrastructure siting area conditions meet safety requirements, the region needs large urban infrastructure, and the region exists clear traffic dominance. Through infrastructure planning in that region will help to improve regional economic development, and improve the living standards of local residents. Encouraged planning area means the area whose infrastructure siting area conditions meet safety requirements, is more appropriate for the construction of infrastructure projects, and fewer existing urban infrastructure. Through infrastructure planning in that region will help to meet regional economic development, and satisfy the living standards of local residents. regional restricted planning area means the area has existence of the certain geological disaster risks, and needs small urban infrastructure, whose infrastructure impact on the regional environment is greater than the benefits of play.

Index system of facilities planning siting function zoning. Indicators facilities planning siting function zoning main used to measure the ability of regional planning conditions, and evaluation the suitability of facilities planning and construction. In order to assess the analyzed region planning condition objectively and accurately, facilities planning siting function zoning indicators must be true reflection of the regional site security, building needs of regional planning and regional planning construction of existing conditions. Therefore, selection the indicators should follow the scientific, systematic, comparable, easy to get and streamlining principles [4-5]. Based on urban infrastructure planning siting requirements, combined with urban characteristics and development status of the study area, this paper intends to determine the distribution of geological disasters in the region, regional population density, type of regional planning and regional transport dominance as a function of zoning index. Index system is shown in Table 1.

Table 1 Index system of planning siting function zoning

	Constrained Layer	Index layer	Quantitative Methods
Index	Regional site security	Distribution of geological disasters	Landslides, mudslides, avalanches hidden spots and dangerous trend level
	Regional planning construction needs	Population distribution	The population density
		Type of urban planning	Level and type of urban functions
	Existing regional planning conditions	Transportation Advantage	Various types of road network density

Index weight calculation. Weights indicate the importance of each evaluation index, which means that each of the different roles the evaluation in overall plays. After building planning siting function zoning index system, we use The analytic hierarchy process to determine the weight of each index. The analytic hierarchy process (The analytic hierarchy process, AHP) is the analysis method for multiple attribute decision making system put forward by America University of Pittsburgh professor T.L.Saaty in the mid 70's, which combines qualitative and quantitative analysis and is simple and effective, making the experience to quantify, as the utility in condition of the complex

factor structure and lack of data case [6]. The algorithm idea is to arranged complex evaluate objects in an whole of orderly hierarchical structure, and make pairwise comparisons and judgment between the various evaluation, and calculate the relative importance of evaluation projects, namely the weights.

Division practices of urban infrastructure siting functional areas in Panzhihua

Status of the study area. Panzhihua City, a municipality directly under the central government in Sichuan Province, is a typical mountain resource type city of our country. Due to the construction principle: "Patron, dispersed, hidden" and into the hole taken to build the city under the particular circumstances, the city's urban development structure is mainly in the line of industrial layout, causing the city's irrational industrial structure and spatial issues [7]. At present, Panzhihua city is in the industry transition, through scientific planning of city space is conducive to change the spatial structure problems left over by history, and rationalization city space layout. While the city infrastructure planning is an important factor to decide the city space layout, therefore, through the functional division to the city infrastructure planning site area, it's conducive to the promotion of industrial economic development of Panzhihua city and the adjustment of industrial structure. Based on increased space utilization, protection of ecological environment and resources is very important to improve the regional development capacity.

Process analysis.

(1) Index system analysis

1) Regional site safety. Panzhihua city is in geological disaster-prone areas, the main types of geological hazards are landslide, debris flow, collapse, in addition, crack, surface collapse, and unstable slope is more. In general, geological disaster has a wide distribution, large-scale disasters and other features. There're a lot of mudslides, landslides, avalanches and other geological disasters occur every year the city, causing huge losses to the city [8]. According to the scale and risk trend of geological disaster, disaster grade were assigned (Table 2).

Tab.2 Exponential assignment of geological disasters

Scale and risk trend of geological disaster	Serious	Heavy	No trouble
Large	0	1	-
Medium	1	2	-
Miniature	2	3	-
None	-	-	5

Tab.3 Exponential assignment of population density

population density	value
≥135	4
85~135	3
45~85	2
＜45	1

Note: The degree of hazard and disaster-scale trend data derived from the "geological disaster prevention planning regulations in Panzhihua City"

2) Regional planning needs. A. Population density distribution. According to the sixth census data in Panzhihua City, population density distribution is divided into four grades, and assigned in Table 3.

B. Town planning type. According to "Panzhihua City Master Plan" (2010-2025) [9], Panzhihua urban system is divided into four towns based on the size of the town and the urban population. Various types of urban planning and development efforts may be in descending order of Industry and Trade, comprehensive, tourism and farmer-type. Towns type assignment is shown in Table 4.

Tab.4 Exponential assignment of town type

Urban grade Urban type	Industry and trade	Comprehensive type	Tourism	farmer
Level 1	8	7	6	5
Level 2	7	6	5	4
Level 3	6	5	4	3
Level 4	5	4	3	2

Tab.5 Exponential assignment of road network density

Range	Value
≥0.45	4
0.3~0.45	3
0.2~0.3	2
＜0.2	1

3) regional transport superiority degree. Considering the 5 counties 44 towns of Panzhihua City as the research unit, calculate the road network density analysis of regional transport superiority degree. According to the road network density formula the township transit network density was calculated. According to the road network density, assignment of the regional road network is shown (Table 5).

the index weight calculation. Calculated function area dividing index weight values were: regional site safety weight 0.52, regional planning and construction demand weight 0.33, regional planning both conditions weight 0.15.

Analysis of the results

Through a comprehensive analysis of Panzhihua City, the landslides, mudslides, landslides and other geological disasters hidden point, population density distribution, urban planning level and planning and construction type for functions of demand regional, as well as traffic dominance cases based on the regional road network density, index weights determined in accordance with AHP, 44 towns of Panzhihua City, will be divided into three different types of site planning functions area. Combined with the types and characteristics of functional areas, various types of planning proposals were given.

Tab.5 Analysis on the various types of functional zones

Types	Region Features	Planning proposals
key planning area	Mainly in towns with industry and trade functions, a small regional geological disaster risks, no large-scale disaster, low degree of geological disasters dangerous trend, facility in siting meet safety; Meanwhile, great regional population density, high level of urban planning, main functions in urban industry and trade; significantly regional transport dominance, improved existing road network structure.	This type of regional planning area should be the focus, to bring the service efficient facilities, and improve facility utilization.
Encouraged planning area	less existed urban infrastructure; no serious risks of geological disasters, low trend of geological disasters dangerous; moderate population density and level of TPB planning, facilities construction demand weaker than key planning areas, main in integrated urban planning types.	Planning and construction of urban infrastructure will promote regional economic growth, and promote regional development. To meet the needs of the premise of the construction of infrastructure, these areas can be priority.
Restricted Planning Area	more geological disaster prone point, major geological disaster; relatively small regional population density, low level of urban planning. Such areas' planning functions are main in farmers and tourism, small infrastructure needs of urban planning and construction; both limited in area construction and conditions, urban infrastructure construction revenue less than the extent of the damage to the ecology.	Only suitable for small-scale of urban infrastructure planning area, but not suitable for large-scale of development and construction, and in small-scale of facilities planning process, it should be priority to followed the principle of protecting and moderately developing.

According to the results of urban infrastructure siting division of functional areas, Panzhihua City space planning site is divided into three different regions, through recommendations for planning of different areas, here provided decision support for the city's urban infrastructure planning. Meanwhile, staggered distribution area in urban infrastructure siting, optimized the pattern of urban space and improved the urban land utilization.

Conclusion

Urban infrastructure siting division planning area is planning method adhering to the concept of the division of main functional areas. This planning method, not only realized the full demonstration of its own characteristics of proposed regional conditions and facility , but also achieved maximum utilization of land resources, optimized the spatial pattern of the city, achieve regional development according to local conditions, has a positive effect of improvement of rationality of urban infrastructure facility siting and enhancement of land space utilization. In this paper, the function area dividing index is based on the study of regional conditions. Taking into account of the regional city planning, it still has some limitations. Various factors should be considered in the next step of the study, it's necessary to further refine for various indicators, improve the rationality and preparation of functional division. This study is to deepen the division of main function region further, and have a meaning of draw lessons of similar research in related fields.

Comparative Study of R&D Spillover Effect for High Technology Industry and Traditional Industry

Fan-jun MENG

(school of management, Tianjin University of Technology , Tianjin 300384,china)
Mfj416@163.com

Keywords: R&D spillover; spatial econometric model; high technological industries; traditional industries

Abstract. Based on economic distance weights matrix, using the R&D input-output panel data sets of high technological industry and traditional industry in 29 provinces in China from 2001 to 2010 and spatial econometric method，this paper analyzes their R&D spillover effects respectively between provinces. The results indicate: Even though R&D in the high technology industry in China are active, the R&D spillover in this industry is lower than that in the traditional industries; R＆D capital contributes to R&D output more than R＆D labor for high technological industry, while the traditional industry is just the opposite.

1 Introduction

New economic growth theory and a large number of empirical studies indicate that R&D is the source of scientific and technological innovation, R&D not only can drive the regional innovation output, and can pass the spillover effects in other parts of the innovation output.

As early as in 1962, Arrow studied on the R&D spillover effect, and thinks that enterprise creates an knowledge is easy obtained by other enterprise, and innovators can't get any compensation [1]. Arrow's description of phenomenon, in fact, is a kind of R&D spillovers,then many scholars analyzing R&D spillover from multiple levels, Griliches (1979) set up R&D spillover effect model measuring technology of distance between the enterprise and the industry on the R&D spillover effect [2], on the basis of the production function created by Griliches,Jaffe introduced the overflow effect, and apply the model to study the regional R&D spillovers, emphasized the geographic space of industry, college and the importance of similar technology[3]. Huang Zhiqi (2013) use the system of generalized moment estimation method to study the research and development and knowledge spillover effect and discrepancy in the high-tech industrial clusters [4], Wang Qingxi (2013) through establish different spatial weight matrix investigated china provincial knowledge spillover effect under different proximity of high technology industry [5].

Through the sorting of literature ,we found that scholars of high technology industry R&D spillover effect using a variety of methods, from the perspective of a variety of research, but ignored the traditional industry R&D spillover effect. We do not deny that the high-tech industry R&D spillover effects on the importance of economic growth, but the traditional industry as the main part of modern industrial economy, it is important for the innovative development of our country and the economic transformation.

2, Model Implications and Interpretation

2.1 spatial panel model

Based on spatial panel data model are mainly the spatial lag model (SLM) the spatial error model (SEM) and spatial Dubin model (SDM). Combining the reality of the article, We establish the following spatial lag model (SLM), the spatial error model (SEM) and space doberman model (SDM)

$$SLM:\ \ln A_{ij} = \xi\sum_{j=1}^{n} w_{ij}A_{it} + \beta_1 \ln L_{it} + \beta_2 \ln K_{it} + \mu_i + \lambda_t + \varepsilon_{it} \quad (1)$$

$$SEM:\ \ln A_{it} = \beta_1 \ln L_{it} + \beta_2 \ln K_{it} + \rho\sum_{j=1}^{n} w_{ij}\Phi_{it} + \mu_i + \lambda_t + \varepsilon_{it} \quad (2)$$

$$SDM:\ \ln A_{it} = \xi\sum_{j=1}^{n} w_{ij}A_{it} + \beta_1 \ln L_{it} + \beta_2 \ln K_{IT} + \theta_1\sum_{j=1}^{n} w_{ij}\ln L_{it} + \theta_2\sum_{j=1}^{n} w_{ij}\ln K_{it} + \mu_i + \lambda_t + \varepsilon_{it} \quad (3)$$

A_{it} represents the output of R&D, L_{it} represents the R&D personnel input, K_{it} represents the capital stock; i represents the space the number of units; T represents the time; α represents intercept, w represents weights matrix; ξ represents the spatial autoregressive coefficients; ρ represents the spatial autocorrelation coefficient; μ represents the area effect, λrepresents the time effect. For the recognition of the above model, Anselin and Florax（1995）put forward the judgment standard of the model: If found in the spatial dependence of inspection, LMLAG than LMERR statistically more significant, and R- LMLAG significant but LMERR was not significant, you can conclude that spatial lag model is the suitable model; On the contrary, if LMERR than LMLAG statistically more significant, and R -LMERR significant but R - LMLAG was not significant, it can be concluded that the spatial error model is appropriate model.[6]

2.2 Spatial weight matrix

Spatial weight matrix represent the interdependencies between the space unit and associated degree, it is essential reasonably choose correct spatial weight matrix measurement[7]. In this paper, we adopted the economic distance weighting matrix .It generally according to the reciprocal of two provinces in per capita GDP gap setting, The greater the GDP gap between the two provinces, the smaller the weight, on the other hand, the greater the weight. Defines as follows $W_{ij} = \begin{cases} \dfrac{1}{|Y_i - Y_j|}, & i \neq j \\ 0, & i = j \end{cases}$

Y represents the i province level of real per capita GDP

3, Data Sources

This article selects the 29 provinces in China during 2001-2010 (Tibet, xinjiang data lack of serious, slightly) on high technology industry and traditional industry R&D input and output data. consider the data availability, the traditional industry data we use data instead of large and medium-sized industrial enterprises in our country.

R&D activities have a variety of output, we use the patent number as the index of R&D output. The R&D activities personnel full-time equivalent as labor input of R&D activities; We choose the capital stock on behalf of R&D capital investment, and we use perpetual inventory method to accounting R&D capital stock.

4, Results

firstly, We should check whether the spatial correlation exists, then research the R&D spillover between different areas. Moran's I index is the most commonly used indicators. After examination, the Moran's I in different space all above 0.2, indicating a spatial correlation. Below we will analyze the different matrix estimation results.

Table 1. Two kinds of industry R - squared

paramete	High-tech industry			traditional industry		
	SLM	SEM	SDM	SLM	SEM	SDM
$\ln L$	0.134 (1.347)	0.073 (0.695)	0.051 (0.505)	0.292*** (4.594)	-0.001 (-0.010)	0.004 (0.045)
$\ln K$	0.694*** (4.521)	0.592*** (3.318)	0.499*** (2.829)	-0.042 (-0.277)	0.118 (0.597)	0.246 (1.140)
$W \times \ln L$	/	/	0.860*** (2.992)	/	/	1.264*** (7.448)
$W \times \ln K$	/	/	0.106 (0.301)	/	/	-0.309 (-1.166)
ξ	0.541*** (9.909)	/	0.246*** (2.684)	0.775*** (22.964)	/	0.314*** (3.911)
ρ	/	0.742*** (17.344)	/	/	0.880*** (42.447)	/
R-squared	0.907	0.813	0.911	0.95	0.724	0.953
sigma^2	0.079	0.083	0.076	0.027	0.028	0.025
LOG-L	-35.58	-49.271	-24.856	109.52	101.145	134.114

* , **, *** *significance at 1%.5%,10%

The table 1shows that under the different models, two kinds of industry R - squared all above 0.7, Model fitting is good, spatial correlation coefficient remarkable, and highly significant under 1% level. Indicates that china economic level similarity between provinces and cities regional R&D has strong space complementary and dependence. it shows that the economic factors on the R&D spillover has an important influence. With the growth of economy, distance barriers for the R&D spillover will smaller and smaller. Even though R&D in the high technology industry in China are active, the R&D spillover in this industry is lower than that in the traditional industries; R＆D capital contributes to R&D output more than R＆D labor for high technological industry, while the traditional industry is just the opposite. Two kinds of industry labor in SDM model spatial lag were significantly positive, shows that labor in similar economic level has positive spillover effect between regions

5, Conclusions

This paper based on Chinese 29 provinces in 2001-2010 high technology industry and traditional industry data, the analysis of the weighting matrix in the space of R&D spillover. The study found that:

High-tech industry R&D activities, the influence of the capital investment on R&D output significantly, it has to do with Wang Qingxi etc. (2013) results consistent, show that R&D output of high-tech industry in China is still mainly depends on capital investment; Input of R&D output has a positive influence on R&D personnel, but much smaller than the capital investment; Unlike high technology industry, the traditional industry R&D activities, labor input coefficient significantly, spillover effect is better than high technology industry. This shows that although the high technology industry's R&D activities more active, but the high technology industry is lower than that of the traditional industry in terms of R&D spillover of R&D spillovers. To sum up, the traditional industry with high technology industry R&D activities is the core of the national innovation system development momentum. Although the influence factors of R&D activity output

both is different, but all have significant spatial spillover effects of R&D, and the traditional industry spillover effect is stronger, if consider absorption capacity and other factors is not easy to measure, the traditional industry spillover is likely to be higher, so we in the emphasis on high technology industry R&D spillovers can't ignore traditional industries at the same time.

A Study on Web-based EVP Teaching Platform

Wenjun ZHANG

Jinhua Polytechnic, Jinhua, 321017, China

email: zhangwenjun.1976@163.com

Keywords: web-based; EVP; platform; the ecological teaching model

Abstract. The current EVP program in China is facing many challenges such as the incomplete teaching reform, misconceptions in the use of network technologies and the lack of in-depth scientific research into English courses and teaching. To address these problems, an ecological teaching model that consists of classroom teaching and teaching in virtual environments by developing a web-based EVP teaching platform is constructed. The teaching platform, designed in accordance with higher vocational college students' characteristics, adopts the course structure of "basic college English +industry-specific English", which is effective to stimulate the students' learning motivation and enhance the teaching quality.

Introduction

Higher vocational education is an important part of higher education in China. It has already accounted for about half of the total higher education in terms of the number of vocational colleges and that of students enrolled [1]. However, higher vocational education in China still has a long way to go in such perspectives as the teaching philosophy, the school system, the teaching contents and the methods. In recent years, EVP (English for vocational purposes) teaching has undergone some reforms in teaching models, shifting from the traditional teacher-centered model to the current student-centered multimedia model [2]. This field has been a focus of concern among college English teachers and researchers and has yielded many research fruits [3][4][5][6]. EVP teaching, however, has not developed relatively sound theories and research so far. There still existed many problems such as the incomplete teaching reform, misconceptions about the use of multimedia network technologies, and the lack of in-depth exploration and research on curriculum and teaching etc. The EVP program needs some breakthroughs before it achieves a leaping development.

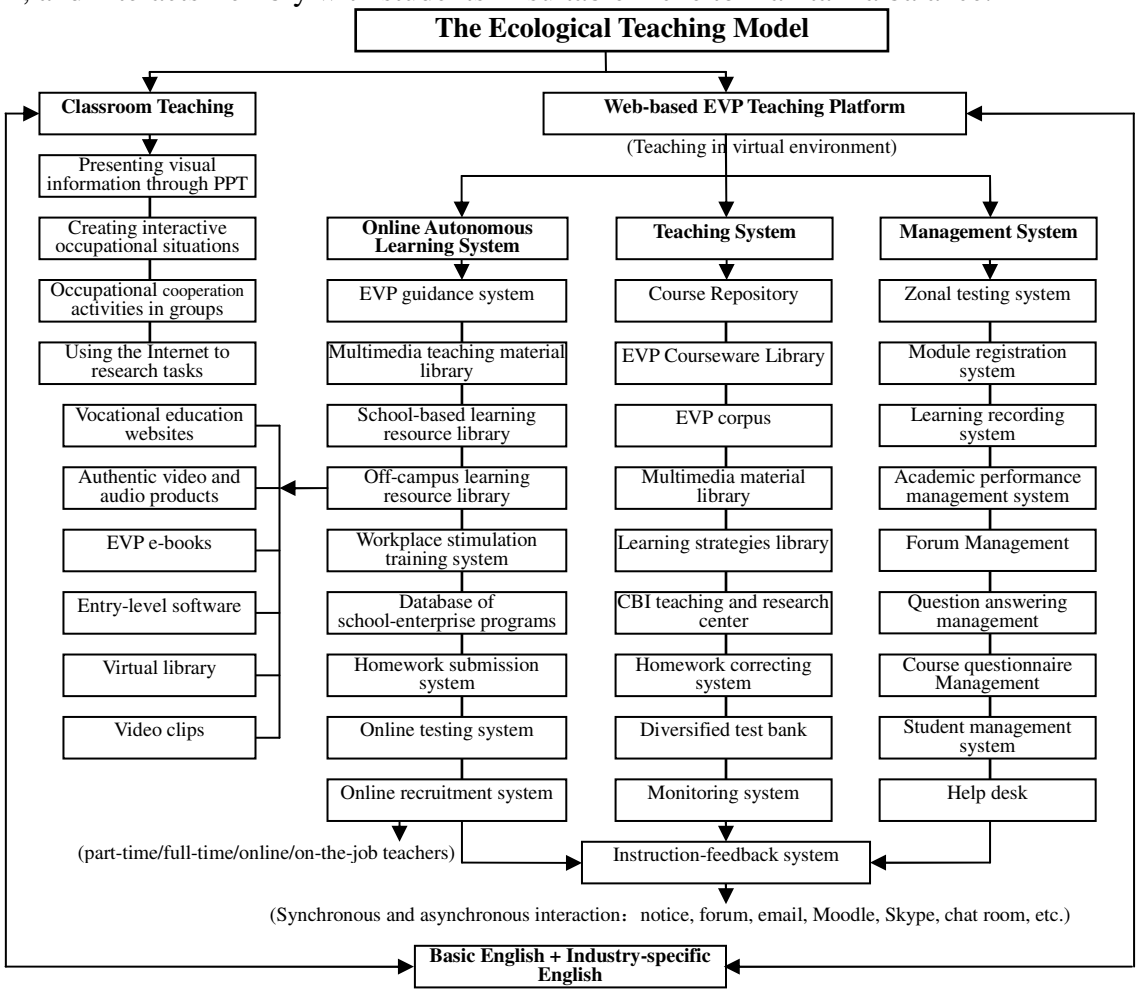
Design of the ecological teaching model

EVP teaching reform can be viewed from the "ecological" perspective [2]. When computer and Internet are integrated into EVP teaching program, many traditional elements (teaching materials, contents, methods, etc.) are replaced by new elements (multimedia, web content, technology and methods, etc.). Thus, the original ecosystem of EVP teaching is broken. To maintain the dynamic harmony and balance of the teaching system, it is essential to stabilize the teaching structure and make teaching elements compatible to each other. It is equally important to timely build ecological teaching model, monitor healthy functioning of teaching, balance the elements of the niche, and promote individual development.

Structure of the model

The structure of the ecological teaching model is as followed in Figure 1. Overall, this teaching model consists of two parts: classroom teaching and teaching in virtual environment. Virtual environment refers to the web-based EVP teaching platform, which is composed of three systems: online autonomous learning system, the teaching system and management system. This model is student-centered as students are the body of learning process and active constructors of knowledge while the instructor is the organizer and mentor, helping and promoting students' construction of meaning. The new model sets up an information-based teaching and learning environment. The

teacher, students, teaching media and teaching contents are the major elements. The teacher fulfills his job of guiding students' learning, teaching and assessing through classroom teaching and virtual platform, and interacts flexibly with students in suitable niche to maintain a balance.



Basic English refers to Integrated English courses, College English Test Band Three, and Practical English Test for Colleges (Level B).
Industry-specific English includes vocational spoken English, Listening for workplace situations, Workplace reading, Vocational practical writing.

Figure 1: Structure of the ecological teaching model

The first interface of network self-learning system is EVP guidance system. This system is, in essence, the unique objectives and plans of each student' vocational English learning at different phases, which are made after the full communication with the instructor based on his own academic achievements in the entrance examination as well as his learning style and learning characteristics. This system emphasizes students' step-by-step process as well as their individual differences. It provides navigation for the learning platform. In the teaching system, the teacher (or teacher team) constructs course repository and EVP courseware library. He can prepare lessons, design and upload assignments, or set up a diversified test bank. He can also make a notice through the feedback system which is shared by the autonomous learning system and management system. Additionally, he can initiate discussions and interactions in the forum, and give synchronous feedback to students through Skype, Moodle or chat rooms. In the CBI teaching and research center, the teacher can publish teaching experiences, share teaching achievements as well as discuss research projects through sharewares like Alfresco, Wiki or teacher blogs. In this way the teacher can promote interactions with his peers and thereby enhance his own teaching and research capabilities. Through the monitoring system, the teacher can observe students' online learning, identify their problems, and guide or help them accordingly.

The management system is a support system for the teaching system and learning system. It enables students to record, monitor, assess and manage their learning process. It is also a help desk.

Course structure

The first step to reform teaching model is to change the course structure. The focus of the reform is to fully incorporate the element of modern information technology into the current structure of English courses (Basic English + industry-specific English) so that multimedia information technology can be utilized in every step of higher vocational English teaching. From the perspective of ecology, such reform aims to put all the elements of the ecological environment in right niche so as to stabilizing the teaching structure and maintaining the ecological balance of the teaching system. It can be seen from Figure 1 that in the new model, the course structure of "Basic English + vocational English" goes throughout the whole teaching process. Basic English, on one hand, enables students to make a link with high school English and improve their comprehensive ability of listening, speaking, reading and writing and get prepared for vocational English learning in the next stage. On the other hand, it prepares students for College English Test Band Three or Practical English Test for Colleges (Level B) required by the syllabus.

Teaching process

The teaching process consists of five parts.

(1) Zonal test of English proficiency. In the orientation week, all vocational students will take a hierarchical test of English proficiency on line. After they submit their answers, the system automatically gives feedback and evaluation. It also makes suggestions on levels and modules that each student should choose.

(2) Register for classes on line. Students complete the registration by choosing the level, modules, and the instructor. The system generates students' ID and password and establishes their e-learning archives.

(3) Study in appropriate level. Students preview the texts on the autonomous learning system and do other extra-curriculum learning according to their own needs.

(4) Study in the classroom. The instructor presents course information through PPT (powerpoint), and encourages students to blend into workplace stimulation learning context, actively engaged in various classroom activities as well as research tasks on the net. The network-based classroom interaction involves six procedures (see Figure 2).

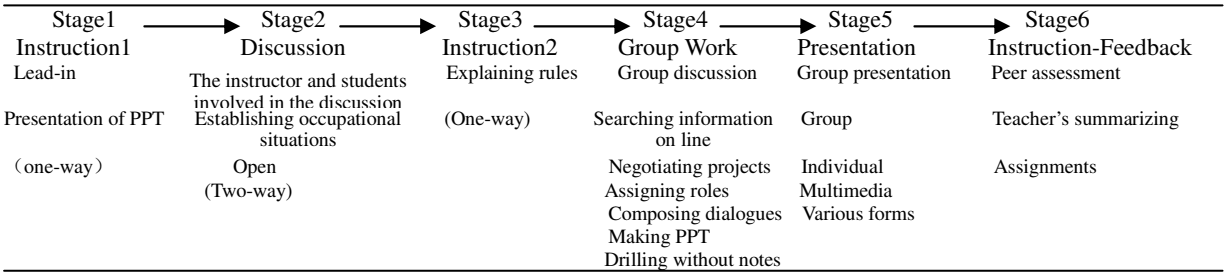


Figure 2: Flow chart for interactive classroom activities

In stage 1, the teacher gives instructions. This is usually a one-way process. In stage 2, the teacher invites and guides students to discuss by posing enlightening questions. This is an open, two-way discussion. Stage 3 is a one-way instruction. The teacher explains rules guiding group activities. Stage 4 is a process of group discussions. By taking the group discussion, students independently complete their tasks. In stage 5, students make group presentation based on the discussion. Stage 6 is a process for the instruction-feedback and peer assessments.

(5) Assessment and testing. Formative assessment is made based on the frequency and quality of students' participation in online discussions, classroom performance, homework, feedback from the firm where students work as interns, and the record of learning process as well. Summative assessment is a comprehensive assessment of language skills, mainly in the form of practical assessment in the end of the semester.

Learning process

Students' learning process consists of four steps. (1) Preview before class. Students' learning material includes those available in EVP multimedia teaching material library, school-based as well as off-campus learning resources library. (2) Classroom learning. (3) Consolidating what they have learned by means of assignments, consulting online library or testing. (4) Training in occupational situation and job interview. Students can use workplace stimulation training system, data-base of school-enterprise programs and online recruitment systems. In the learning process, students can communicate with the teacher, classmates and network administrators and receive feedback from them as well through the communication-feedback system. Students can either communicate with others through such non-real-time interaction ways as messages, emails or BBS, or make synchronous video communication through Skype or Moodle in agreed office hours. Students have access to a very rich source of vocational English knowledge, including vocational education website, the original audio and video products, and EVP e-books.

Conclusion

The ecological teaching model is employment-oriented. Through the web-based teaching platform, computer and network technologies are integrated into the whole process of EVP teaching, and become an indispensible organic part of the teaching model. The philosophy of ecological education permeates every link of English teaching. The model shows respect for individual difference and diversity of life. It attaches importance to personalized learning process and diversified evaluation methods. It is an open and comprehensive foreign language teaching system combining learning and practicing. It updates the concepts of traditional teaching model and inherits some advantages at the same time, and it is helpful to solve the problems existed. Of course, teaching reform is by no means easy. As English teachers, we must strive to foster strengths and circumvent weaknesses and constantly make exploration and improvement. With the rapid development of computer and network technologies, the potential for the development of web-based foreign language teaching is immeasurable.

Keywords: private bank; risk management capacities; evaluation index system

Abstract. With the gradual deepening of financial reform in China, the development prospect of private banks is bright. However, the fierce competition in the banking sector and the nature of the private banks themselves make them face complex and diverse risk. Thus, it's particularly important to construct a reasonable evaluation index system of risk management capacities of private banks to reach an objective and clear evaluation of risk management level.

Introduction

In 2013, China's financial sector reform has achieved a new level. The 3rd Plenum of the 18th CPC pointed out relaxing private bank entry threshold and promoting the reform of RMB exchange rate formation mechanism. The establishment of China (Shanghai) Pilot FTZ aims to explore the new path and model of China's opening to the outside world, and to deepen the open innovation in the financial sector. In recent years, China's private economic grows stronger continuously; private capital markets gradually become active. CBRC offers proposals on encouraging and guiding private capital to banking. The State Council points out let private capital launch private banks, financial leasing companies and consumer finance companies or other financial institutions at their own risk. These new policies above provide opportunity to the establishment and development of private banks.

However, private bank in China is still a new thing which is inexperienced in many aspects; what's more, a series of financial opening policies make the sources and types of risks become more complex. Therefore, it's particularly important that private banks could understand their own risk management capabilities objectively and clearly.

Literature Review

In the study of private banks, many scholars make a study of the feasibility and future strategies. Ma Yuanyue[1](2004) pointed out moral hazard was prominent in all risks of private bank and gave the financial regulation initiatives. Xia Biying[2](2011) analyzed risk control mode of several private banks in Taizhou, put forward the private banks in China should perfect the governance structure, improve business strategy, and transform growth mode to strengthen the credit risk management.

In the study of risk management capacities of private banks, Liang Lijun[3](2010)pointed out that the evaluation of the bank's operational risk management ability can be divided into head office management level, department level, staff level and environment level. Ni Biao[4](2013) considered innovative companies need manage scientifically significant risk to maintain continuous innovation.

Different aspects and methods were used in private bank and risk management capabilities. However, few scholars combine private bank with risk management capability to build quantifiable evaluation index system and the corresponding evaluation method.

Connotation of Private Bank Risk Management Capabilities

Particularity of private bank risks.

Public trust risk. Private bank is different from state-owned commercial bank; it has no national prestige support, which means it has a greater risk of public trust than general commercial bank.

Industry competition risk. The competition covers deposit-taking business, management talent, financial services and technological innovation. Private bank must keep constant innovation, improve service quality, and increase public trust to have a larger space for development.

Capital shortage risk. Whether capital is adequacy determines whether the banks have strong economic strength and solvency. Private bank just has a single capital source at its inception, economic strength is limited. It must expand the various channels to boost capital, as soon as possible to promote business.

Insufficient funds risk. Since private bank has weak financial strength and low public trust at its inception, deposit business performance is not optimistic. The constant deepening of financial reform in our country, the increasing of financial institutions and the limited deposit resources lead to the greater risk of insufficient funds.

Associated loans risk. Most private enterprises set up private bank for providing financing channels and facilities to the enterprise. However these enterprises which are small and fund-limited have weak anti-risk capabilities, and they cannot repay the loan with a bit careless.

Connotation of risk management capabilities. Private bank risk management capabilities mean that private bank possess the knowledge and skills for risk management goal. Private bank reduce the probability of loss and enhance competitiveness by its general and specific risks management. To enhance the efficiency of risk management for private bank is good to establish a good reputation and to gain a larger market.

Private Bank Risk Management Capability Evaluation Index System

According to the index selection principle and characteristics of private bank, the paper builds three layers of evaluation index system.

Table 1 Private bank risk management capability evaluation index system

target	element	index
private bank risk management capability	risk assessment C_1	assessment method C_{11}
		assessment index system C_{12}
		assessment criteria C_{13}
		assessment process C_{14}
	risk monitoring C_2	:internal audit C_{21}
		monitoring mechanisms C_{22}
		risk tracking C_{23}
		department supervision C_{24}
	risk prevention C_3	NPL coverage C_{31}
		diversification rate C_{32}
		capital adequacy ratio C_{33}
		short-term loans ratio C_{34}
	risk response C_4	emergency level C_{41}
		company scale C_{42}
		profit margin C_{43}
		risk aversion C_{44}
		risk transfer C_{45}
		risk compensation mechanism C_{46}
	managerial	risk management concept C_{51}

communicationC_5	risk management system C_{52}
	risk management information system C_{53}
	risk management organizational structure C_{54}
	staff's quality C_{55}
	communication efficiency C_{56}

Risk assessment. Private bank takes certain risk criteria and method to evaluate measure for risk size and risk occurrence probability and the relative importance in order to identify risk factors and consequences.

Risk monitoring. Internal audit is an independent inspection, supervision and evaluation activities. The establishment of the monitoring mechanism is to supervise and control the risk management process. Risk tracking management can improve the force of recognizing the old and new risk. Private bank need to be limited and monitored by CBRC and other specific institutions. This regulation can promote private banks managing risk more effectively.

Risk prevention. NPL coverage mainly reflects the private bank's ability to compensate for loan losses and prevent the loan risk. Enterprises need as much as possible to avoid risk concentration in the process of business, appropriately disperses risk to other institutions. Capital adequacy ratio reflects the ability of private bank to make up for the loss of creditors with their own capital.

Risk response. Private bank should have emergency management system, including recognition, early warning, monitoring, treatment, prediction, etc. Scale of private bank directly reflect its overall strength, the larger the scale, the stronger the strength of its ability to cope with risk. Profit is the basis of the banks to survive. In order to reduce or avoid loss caused by risks, private bank usually takes certain measures of prevention and post-processing to avoid risk. Risk transfer means that the private bank takes some measures to make other organizations or individuals to undertake its original part or all of the risks and losses. At the beginning of establishment of the bank, related departments should establish some compensation mechanism.

Managerial communication. This part mainly involves management hardware and communication software.

For quantitative index, the data can be got from bank annual report or related institutions; for qualitative index, the data can be got by the expert scoring method.

Private Bank Risk Management Capability Evaluation Method

The influence factors of private bank risk management ability are numerous; the factors interact with each other. The paper use extension synthetic evaluation method to evaluate the private bank risk management capability. “Things, index, value” is the main content of the extension synthetic evaluation method. Assume T represent evaluation object name, C represent characteristic index, and V represent the value of C. Q= (T, C, V) constitutes the basic unit of describing things. The steps of extension model as follows:

Step 1: Determine the classical domain and joint domain of the model

According to the evaluation index C, the private bank risk management capability indexes are divided into m standard classes.

$$Q_p=(T_p,C_i,V_{pi})=\begin{bmatrix} T_p & c_1 & v_{p1} \\ & c_2 & v_{p2} \\ & \vdots & \vdots \\ & c_n & v_{pn} \end{bmatrix}=\begin{bmatrix} T_p & c_1 & (a_{p1},b_{p1}) \\ & c_2 & (a_{p2},b_{p2}) \\ & \vdots & \vdots \\ & c_n & (a_{pn},b_{pn}) \end{bmatrix} \quad (i=1,\,2,\,\cdots,\,n) \tag{1}$$

T_p is for private Banks risk management capability, V_{pi} is for value range of C_i, namely $\langle a_{pi},b_{pi}\rangle$. Q_j is for j level risk management capability of matter-element extension evaluation model. T_j is for lower than j level risk management capability. $(i=1,\,2,\cdots,n\,;\ j=1,\,2,\cdots,m)$

Step 2: Establish correlation functions

$$\pi(v_i, v_{ji}) = \left| v_i - \frac{a_{ji} + b_{ji}}{2} \right| - \frac{1}{2}(b_{ji} - a_{ji}) \quad (i = 1, 2, \cdots, n;\ j = 1, 2, \cdots, m) \tag{2}$$

$$\pi(v_i, v_{pi}) = \left| v_i - \frac{a_{ji} + b_{ji}}{2} \right| - \frac{1}{2}(b_{pi} - a_{pi}) \quad (i = 1, 2, \cdots, n;\ j = 1, 2, \cdots, m) \tag{3}$$

$\pi(v_i, v_{ji})$ is for the proximity of v_i and v_{ji}, $\pi(v_i, v_{pi})$ is for the proximity of v_i and v_{pi}. If $\pi(v_i, v_{ji}) \geq 0$, v_i is outside of v_{ji}, if $\pi(v_i, v_{ji}) \leq 0$, v_i is inside of v_{ji}.

$$K_j(c_i) = \begin{cases} \dfrac{\pi(v_i, v_{ji})}{\pi(v_i, v_{pi}) - \pi(v_i, v_{ji})} & v_i \notin v_{ji} \text{ and } \pi(v_i, v_{pi}) \neq 0 \\ \dfrac{-\pi(v_i, v_{ji})}{|v_{ji}|} & v_i \in v_{ji} \\ -\pi(v_i, v_{ji}) - 1 & v_i \notin v_{ji} \text{ and } \pi(v_i, v_{pi}) = 0 \end{cases} \tag{4}$$

$K_j(c_i)$ is the correlation of c_i and level j.

Step 3: Determine the index weight

The paper uses fuzzy chromatography analysis to determine the index weight. The experts with their understanding of the evaluation objects give the evaluation opinion; the index weight is calculated on the basis.

Structure judgment matrix between elements layer and target layer and index layer and element layer. Sort for each layer; calculate the element weight of each layer. Sort for total layers; calculate the weight of each index compared with the evaluation target.

Step 4: Layer calculation

Assume $w_i (\sum_{i=1}^{n} w_i = 1)$ is the index weight coefficient, the correlation function of private bank capability is: $K_j(M) = \sum_{i=1}^{n} w_i K_j(v_i)$; $j = 1, 2, \cdots, m$.

Total correlation function of risk management capability is: $K(M) = \max_{1 \leq j \leq m} K_j(M)$.

Conclusion

Based on the new policies and measures and general and special risk analyses faced by private bank, the paper builds the evaluation index system of private bank risk management capacity, and selects the corresponding evaluation method. The paper can provide evaluation and decision-making basis to private bank and the relevant departments, provide reference to similar financial institutions, also make the commercial bank risk management theory and evaluation system more rich and perfect.

Keywords: Network Teaching Pattern, Module Division, Vocational Qualification Certificate

Abstract. The network teaching creates new education and teaching idea and brings huge impact and challenges to the traditional education pattern. This paper studies the webpage making courses under the network teaching pattern, proposes modular and phase teaching idea, inspires learning interests of students, exercises innovative ideas of students and improves teaching quality with student as the guide.

Introduction

With increasing development of network technology, the network applications are becoming extensive and extensive and the websites have become one important platform for information demonstration of the companies, enterprises or individuals. For college students majoring in the computer, it is very practicable and important to grasp webpage making method and website concurrency technology, which can extensively expand their employment areas and improve their employment competition capability. As one foundational course for occupational skill of the computer specialty, the webpage making courses can cultivate the webpage design, webpage making and website management capability of the students and is a very practicable and comprehensive course.

Problems in teaching of webpage making course

The webpage making course is a very technical, applicable and practicable course, but now traditional class teaching pattern is used in many colleges, namely teachers instruct by the steps in the teaching material and then students practice them on the computer. The traditional teaching pattern can play the dominant role of teachers and monitor the whole teaching process, but it ignores the main role of students, reduces learning interests of students, and is unfavorable to cultivation of the innovation thinking and capability of students.

With increasing development of information technology, the teaching plans of colleges are experiencing continuous reforms. The computer specialties are developing to the high-end and front technology area. The webpage making courses are cut down in the computer specialties due to limited course class hours, so students have not opportunities to learn webpage making knowledge and skills, so they are lack of webpage making capabilities.

Teaching reform scheme of webpage making course under network teaching pattern

For the above cases, the authors propose the teaching reform scheme of the webpage making courses under the network teaching pattern. This scheme mainly explores the teaching pattern under the network teaching pattern in which the students mainly learn by self via the network teaching platform and the teachers instruct students in 6-8 class hours in the classroom as the auxiliary means. Finally students learn the basic knowledge and operation skills on webpage making and make the medium-size websites. This scheme not only offsets the insufficient teaching periods of the webpage

making source, but also improve self-learning capability, actual practice capability and webpage making skills much.

Reform of teaching contents. The webpage making course is a comprehensive course and involves many aspects such as webpage making, image art and code programming. The teaching contents of webpage making course are divided into different modules, so teaching contents are simple and specific, are clear in thinking, reduce self-learning difficulties of students and assist students to arrange learning keys. The webpage making courses are divided into eight modules, shown as the figure 1.

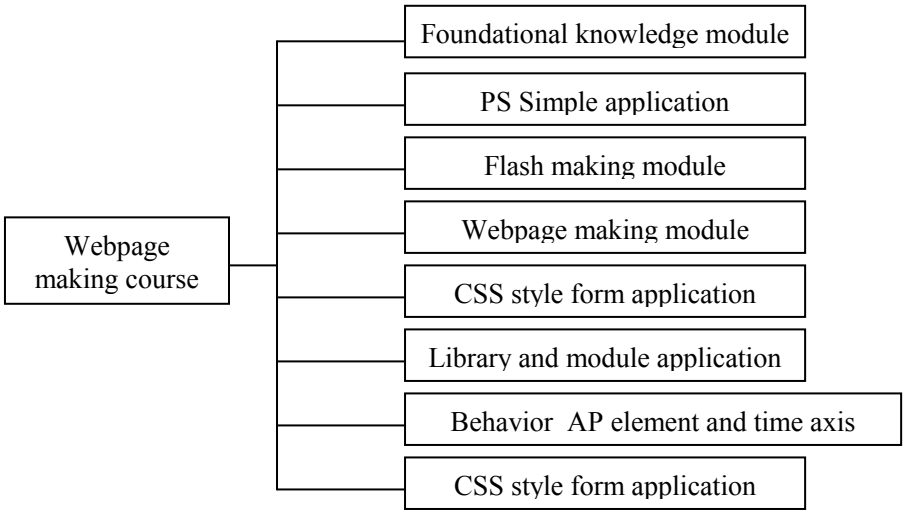

Figure 1 Eight module diagram

All modules are independent of each other and associated with each other. Independence indicates that each module is a complete key and includes independent module ppt and teaching case. An individual module job is designed for each module. Association indicates mutual relation among modules. All knowledge keys are arranged from shallow to deep. All modules coordinate with each other to complete final teaching target.

Each module is taught with the task-driven method. After a student completes self-learning task of each module, he should complete the "tasks" specified by the teacher, namely module jobs. Self-learning capability, practice operation capability and independent exploration spirit of students is cultivated in "task" completion process. Teachers deploy modular jobs via the network teaching platform. Students submit "task" achievement via the network teaching platform. Teachers inspect "task" achievements from students and feed back to students in time to urge students to complete necessary learning of necessary teaching contents and improve network teaching quality.

Reform of teaching form. The network teaching pattern mainly utilizes openness and interactivity of network teaching and richness of network reaching resources, offsets the weakness "students learn what teachers teach" under the traditional teaching pattern, inspires learning interests of students and exercises innovative thinking of students.

（1）Openness of network teaching: The network teaching makes student be free of time and location restriction and students can flexibly and independently learn and repeatedly learn the difficult knowledge keys.

（2）Interactivity of network teaching: the network teaching platform features a better interactivity and can be used for exchange and learning between teachers and students and between students.

（3）Richness of network teaching resources: the network teaching platform not only includes courseware made by the teachers in our college, but also links fine course website of many key colleges, technology forum website, excellent enterprise website and material websites for students to learn.

Reform of assessment pattern. The assessment of the network teaching of the webpage making course focuses on and emphasizes whole-process examination of students. Student learning is tracked

and managed via modular jobs. After students learn all modules, the modular jobs can be combined into a comprehensive website as the examination work. Students can also participate in webpage designer examination organized by Ministry of Industry and Information. Flexibly assessment regulation alleviates examination load of students and implements the idea of "quality education and capability cultivation".

Implementation process of teaching reform

The network teaching pattern of webpage making course is divided into pre-course preparation, student self-learning phase, teacher face-to-face teaching phase and student assessment phase.

Pre-course preparation. The pre-course preparation phase is mainly completed by teachers. Teachers propose course teaching reform scheme, make teaching plan, prepare teaching materials, perfect network teaching platform and organize students to register and select courses.

（1）Make network teaching reform scheme: make network teaching outline and teaching progress, and make teachers know teaching target and teaching contents and grasp teaching progress and make students know teaching form and teaching requirements by making teaching scheme.

（2）Prepare teaching documents: prepare modular teaching ppt and each modular job, collect teaching instances via network resources and prepare the teaching question database.

（3）Perfect network teaching platform: perfect the network teaching platform, store the teaching documents, teaching requirements and teaching progress on the network teaching platform and guide students to learn by self via the network platform according to the teaching progress.

（4）Organize students to register voluntarily: organize students to join voluntarily and propose requirements.

Student self-learning phase. Self-learning phase of students is completed by students. Students learn by self via the network platform, complete modular jobs, participate in interaction between teachers and students, read the network teaching instances and know theory knowledge on webpage making course via the question database.

Teacher face-to-face teaching phase. After students complete all courses, teachers can provide face-to-face teaching during 6-8 class hours. The face-to-face teaching mainly explains problems in the student modular jobs. Teachers will instruct students to make a real website with a comprehensive website as one example.

Student assessment phase. After students complete all learning tasks, they should submit a complete website job for term examination. Students can also participate in webpage designer examination organized by Ministry of Industry and Information.

Conclusions

The network teaching pattern is a new teaching pattern, overcomes the weaknesses in the traditional face-to-face classroom teaching, fully utilizes the network teaching resources, solves urgent campus resources and insufficient course class hours in the colleges, improves comprehensive development of learning proactivity, thinking capability and personality of students, and enhances self-learning capability of students.

Technical Risk Assessment of Large-scale Construction Project Based on Triangle Whitening Weight Function

Ma Wei[1]

Department of economics and management from Tianjin university of science and technology, Tianjin

maweilwtg@126.com

Keywords: large-scale construction project, technical risk assessment, triangle whitening weight function

Abstract. Technical risk assessment model of large-scale construction project has been established by using triangle whitening weight function of grey theory against the problems of technical risk assessment of large-scale construction project. In the end, through example verification, this model is approved to be feasible and have certain value of reference and utilization in similar problems.

Along with the development of scientific technology and the demand of urban modernization, more and more high and new technologies have been applied to large-scale construction project. However, while pursuing for multiple functions and high compatibility, the high and new technologies also have brought higher risk to construction of large-scale construction projects. More complicated engineering and newer technology will lead to higher technical risks. The insufficient estimation to technical risk often leads to great influence on final utilization, maintenance, cost and progress of large-scale construction project.

During construction of large-scale construction project, the technical risk assessment is often lack of necessary historical data and faces the problem of "inadequate and deficient information": technology is neither clear nor certain in itself, it has a portion of known information and a portion of unknown information; the solution of technical risk assessment is featured by differentiation and non-uniqueness and the experience, identification ability and cognitive level of human being are also limited. All these fully demonstrate the "grey" [1] nature of technical risk assessment. Therefore, on qualitative basis, this article uses grey system theory and methods to make quantitative analysis on technical risk assessment of large-scale construction project.

Grey assessment method based on triangle whitening weight function [2]

Suppose there are n objects, m assessment indexes and s grey clusters, then the sample observation about index j of object i is $a_{ij}\ (i=1,2,\ldots,n;\ j=1,2,\ldots,m)$.

Main procedures of grey assessment method based on triangle whitening weight function are as follows:

1) Divide the value range of each index into s grey clusters based on the number of grey clusters required by assessment. For instance, the value range of index j $[a_1, a_{s+1}]$ can be divided into $[a_1,a_2],\cdots,[a_{k-1},a_k],\cdots,[a_{s-1},a_s],[a_s,a_{s+1}]$, among which, the value of $a_k\ (k=1,2,\cdots,s,s+1)$ can be generally determined by requirements of actual situations.

2) Suppose the whitening weight function value of $\lambda_j^k=\left(a_j^k+a_j^{k+1}\right)/2$ of cluster K is 1, connect $\left(\lambda_j^k,1\right)$ with a_j^{k-1}, the start of grey cluster k-1, and a_j^{k+2}, the end of grey cluster k+1 (see in Figure 1) to get the triangle whitening weight function on grey cluster k of index j $f_j^k(x)\left(j=1,2,\cdots,m;k=1,2,\cdots,s\right)$.

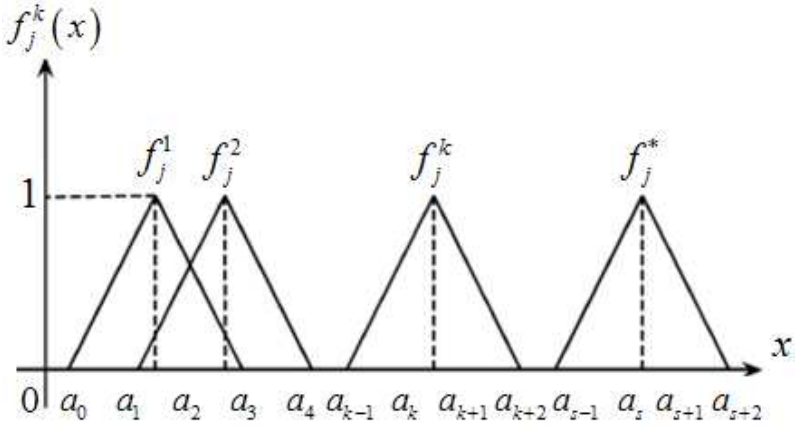

Figure 1 Triangle Whitening Weight Function

3) As to $f_j^1(x)$ and $f_j^s(x)$, the range of index value can be extended to the left and right till a_j^0 and a_j^{s+2} respectively; while for the index observation value x_j, based on the following formula, we can get the whitening weight function value $f_j^k(x)$ of grey cluster k.

$$f_j^k(x)=\begin{cases} 0 & x\notin\left[a_j^{k-1},a_j^{k+2}\right] \\ \dfrac{x_j-a_j^{k-1}}{\lambda_j^k-a_j^{k-1}} & x\in\left[a_j^{k-1},\lambda_j^k\right] \\ \dfrac{a_j^{k+2}-x_j}{a_j^{k+2}-\lambda_j^k} & x\in\left[\lambda_j^k,a_j^{k+2}\right] \end{cases} \tag{1}$$

4) Calculate the comprehensive cluster coefficient σ_j^k of object $i(i=1,2,\ldots,n)$ in grey cluster k:

$$\sigma_j^k=\sum_{j-1}^{m}f_j^k\left(x_{ij}\right)\cdot\eta_j \tag{2}$$

Among which, $f_j^k\left(x_{ij}\right)$ is the whitening weight function of object i in grey cluster k of index; η_j is the weight of index j in comprehensive cluster and can be estimated by experts with fuzzy analysis.

5) With $\max\limits_{1\le k\le s}\left\{\sigma_j^k\right\}=\sigma_j^{k^*}$, we can determine that object i belongs to grey cluster k^*. If there are many objects in grey cluster k^*, then we should confirm the position of each object according to the value of comprehensive cluster coefficients.

Technical risk assessment of large-scale construction project based on triangle whitening weight function

Now, taking technical implementation of a large-sale construction project as the example, we make assessment on technical risk of this project by triangle whitening weight function.

1）Through consulting, statistics and collection of information, in reference to opinions of experts, we set up the index set of the analyzed system [3-4] as shown in Table 1.

Table 1 Index System of Technical Risk Assessment of Large-scale Construction Project

	Structural index	Analysis index
Index system of technical risk assessment of large-scale construction project	Technical maturity (x_1)	Maturity of key technology (x_{11})
		Reserve of related technology and materials (x_{12})
	Technical complexity (x_2)	Breadth of related technologies that have been mastered (x_{21})
		Compatibility of technical integration (x_{22})
		Whether the technology can be easily mastered by construction personnel or not (x_{23})
	Technical reliability (x_3)	Service life (x_{31})
		Maintainability (x_{32})
	Technical foresight (x_4)	Very conform to development tendency (x_{41})
		Whether it has further development potential or not (x_{42})
		Can it be protected by strict intellectual property right? (x_{43})

2）According to the requirements of assessment, this index can be classified into 4 grey clusters: low risk V_1, medium risk V_2, high risk V_3 and rather high risk V_4.

In technical risk assessment, many indexes are qualitatively determined[5]. Since they cannot be calculated directly with quantitative indexes, a certain conversion rule is required. Psychologist G. A. Miller proved by experiment that when judging a program in terms of a certain feature, the number of level that can be correctly identified by ordinary people is from 5 levels to 9 levels, so, the index in word is usually described as the judging index from 5 levels to 9 levels subjecting to specific requirements. So, 1-9 scaling method is introduced to define the qualitative analysis by quantitative numbers. See the meaning of each level in Table 2.

Table 2 1-9 Scaling Method

Definition	Very bad	Bad	Ordinary	High	Very high	Between adjacent definitions
Scale	1	3	5	7	9	2,4,6,8

According to technical integration information owned by the construction group about this large-scale construction project, in reference to the opinions of experts, we grade each index and get a set of realizations of all indexes: index x_{11}, x_{12}, x_{21}, x_{22}, x_{23}, x_{24}, x_{31}, x_{32}, x_{41}, x_{42} and x_{43}, respectively corresponding to 5.9, 8.1, 6.5, 4.3, 6.8, 7.0, 7.2, 8.0, 6.8 and 6.0.

Based on the above, according to the index system of technical risk assessment of large-scale construction project listed in Table1 and by discussion of experts, the analysis value index system of technical risk assessment of this large-scale construction project has been set up as shown in Table 3.

Table 3 Analysis Value of Technical Risk Assessment of Large-scale Construction Project

Index x		Weight η	Rather high risk V_4	High risk V_3	Medium risk V_2	Low risk V_1
Technical maturity (x_1)	x_{11}	7	[1, 2.5]	[2.5, 4]	[4, 6]	[6, 8]
	x_{12}	8	[1, 3]	[3, 5]	[5, 7]	[7, 9]
Technical complexity (x_2)	x_{21}	7	[1, 3]	[3, 5]	[5, 7]	[7, 9]
	x_{22}	6	[1, 4]	[4, 6]	[6, 8]	[8, 9]
	x_{23}	6	[1, 4]	[4, 6]	[6, 8]	[8, 9]
Technical reliability (x_3)	x_{31}	7	[1, 4]	[4, 6]	[6, 8]	[8, 9]
	x_{32}	6	[1, 3]	[3, 5.5]	[5.5, 8]	[8, 9]
Technical foresight (x_4)	x_{41}	5	[1, 3]	[3, 5]	[5, 7]	[7, 9]
	x_{42}	4	[1, 4]	[4, 6]	[6, 8]	[8, 9]
	x_{43}	2	[1, 4]	[4, 6]	[6, 8]	[8, 9]

According to the value index system shown in Table 3, the calculation of triangle whitening weight function is the same as formula (1). If j=1, we can extend the value range of x_{11} to $a_{11}^0 = 0.5$ and $a_{11}^6 = 8.5$, and respectively get four threshold values: rather high risk V_4, high risk V_3, medium risk V_2 and low risk V_1, namely,

$a_{11}^1 = 1$, $a_{11}^2 = 2.5$, $a_{11}^3 = 4$, $a_{11}^4 = 6$, $a_{11}^5 = 8$.

Take the average value of a_1^k and a_1^{k+1} as λ_1^k,

$\lambda_1^1 = 1.75$, $\lambda_1^2 = 3.25$, $\lambda_1^3 = 5$, $\lambda_1^4 = 7$

Put the number into formula (1) and get the whitening weight function $f_1^1(x)$.

$$f_1^1(x) = \begin{cases} 0 & x \notin [0.5, 4] \\ \dfrac{x_1 - 0.5}{1.75 - 0.5} & x \in [0.5, 1.75] \\ \dfrac{4 - x_1}{4 - 1.75} & x \in [1.75, 4] \end{cases}$$

Similarly, we can get the function of $f_1^2(x)$, $f_1^3(x)$ and $f_1^4(x)$.

Respectively put the value of key technical maturity $x_{11} = 5.9$ to the above four whitening weight functions to get the value of whitening weight function of key technical maturity index x_{11} against the 4 grey clusters, “rather high risk”, ” high risk”, “medium risk” and “low risk”:

$f_1^1(5.9) = 0$; $f_1^2(5.9) = 0.036$; $f_1^3(5.9) = 0.7$; $f_1^4(5.9) = 0.63$

From the result of index x_{11}, we can see that the risk of key technical maturity is in “medium” level.

Take the value extension of various indexes in the whole index system and calculate their whitening weight functions against the four different grey clusters, as shown in Table 4.

Table 4 Value of Whitening Weight Function

Index	x_j^0	x_j^6	f_j^1	f_j^2	f_j^3	f_j^4
x_{11}	0.5	8.5	0.000	0.036	0.700	0.630
x_{12}	0.5	9.5	0.000	0.000	0.300	0.930
x_{21}	0.5	9.5	0.000	0.167	0.830	0.000
x_{22}	0.5	9.5	0.486	0.825	0.900	0.000
x_{23}	0.5	9.5	0.000	0.600	0.930	0.320
x_{31}	0.5	9.5	0.000	0.667	1.000	0.400
x_{32}	0.5	9.5	0.000	0.730	0.111	0.500
x_{41}	0.5	9.5	0.000	0.000	0.330	1.000
x_{42}	0.5	9.5	0.000	0.600	0.930	0.320
x_{43}	0.5	9.5	0.000	0.667	0.667	0.000

With formula (2), we can get the comprehensive cluster coefficient of grey cluster K of this large-scale construction project, as stated below:

$$\sigma_j^1 = \sum_{j=1}^{10} f_j^1\left(x_{ij}\right) \bullet \eta_j = 2.916$$

$$\sigma_j^2 = \sum_{j=1}^{10} f_j^2\left(x_{ij}\right) \bullet \eta_j = 22.754$$

$$\sigma_j^3 = \sum_{j=1}^{10} f_j^3\left(x_{ij}\right) \bullet \eta_j = 38.460$$

$$\sigma_j^4 = \sum_{j=1}^{10} f_j^4\left(x_{ij}\right) \bullet \eta_j = 25.850$$

By virtue of $\max\left\{\sigma_j^k\right\} = \sigma_j^3 = 38.460$, we can know that the comprehensive technical risk of this large-scale construction project is in “medium risk” level. Seen from the data in Table 4, the maintainability, technical compatibility and intellectual property right protection of technical risk of this large-scale construction project are in or on the verge of the “high risk” grey cluster, so these aspects still need close follow-up and it is necessary to pay close attention to them during construction for further reduction of technical risk.

Conclusion

This article discusses the feasibility to carry out technical risk assessment of a large-scale construction project by triangle whitening weight function, so as to provide an effective approach and solution for technical risk assessment of large-scale construction project. However, triangle whitening weight function theory still needs further improvement in itself, e.g. the intersection of two grey clusters or above. The reference [2] has brought up a method for improvement called center-point triangle whitening weight function and it is worth learning. Besides, since this method is featured by simple principle, easy operation and high practicability, it is worth promotion in the area of project management and decision-making analysis etc.

Keywords: Analytic Hierarchy Process; Safety Evaluation; System Design

Abstract. Chinese expressway construction security situation is grim at present. Based on the index system, determining the importance of every factor on each level by the experts scoring method and 1-9 scale law. A expressway construction security evaluation system is designed and developed using Analytic Hierarchy Process(AHP) and the modern computer-aided technology, and finally validated. The results show that this system accurately indicated the safety situation of expressway construction, and realize systematism, standardization and automatization of safety evaluation.

Introduction

Along with the large scale construction of expressway in china, the construction security situation is grim, and accidents happen so frequently. To prevent and reduce accidents, safety evaluation of the construction process must be incorporated into the safety evaluation of Highway Engineering [1]. Especially expressway construction project in the mountainous area with bad geological conditions, extra-long tunnels, long-span bridges, steep slopes and other hazardous factors. Through designing and developing the expressway construction safety evaluation system, it can evaluate the risks of construction process, and adopt the corresponding countermeasure to avoid safety accidents. It proved to be effective, and can reduce the engineering risk, prevent and control accidents, ensure the life and property safety of working staff.

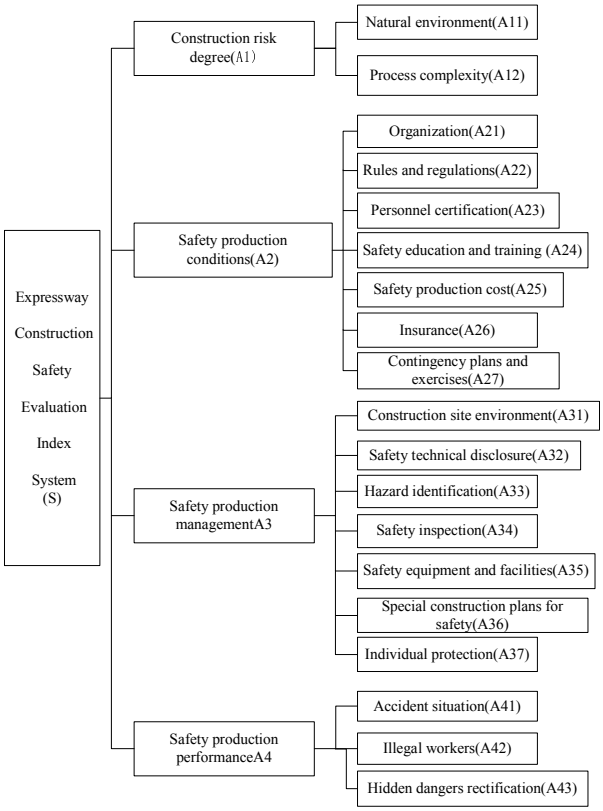

Fig 1.Index system

Establishing evaluation system and Modeling

Establishing evaluation system

Construction objects, construction environment, equipment, personnel, facilities and operations are considered as the main criteria in highway construction. With construction progress, some factors are static, but more dynamic, which is a complex system [2]. In order to evaluate the security situation in the production, it is important to establish a comprehensive, scientific, rational and typical evaluation system for highway construction.It is shown as Fig 1.

Modeling

It is can be seen the evaluation index evaluation system is divided into three layers.In order to improve the evaluation system reliability and quantitate, based on Analytic Hierarchy Process with 1-9 scoring scale and expert-scoring way, the evaluation system, which evaluate risk factors in the highway construction site, is established.

(1) Dividing the hierarchy

The model has a two-step approach. First, the main attributes (construction risk degree, safety production conditions, safety production management and safety production performance) are identified. Second, 19 alternative for each criterion, shown as Fig 1..

(2) Determining the matrix structure

In order to reduce human and other subjective factors on the weights, the evaluation model by constructing judgment matrix approach for each index weights are constructed. The basic assumption of AHP is the reciprocity of the pairwise comparisons:

$$\sum_{i=1}^{n}\sum_{i=1}^{n} a_{ij} = 1, \quad a_{ij} \geq 0, \quad a_{ij} = 1/a_{ji}, \quad (i, j=1,2,3,....n) \qquad (1)$$

1) 1-9 scale assignment. Using Professor Thomas L. Saaty 1-9 scale proposed method [3]for the assignment, a number of experts are invited to assess the relative importance of each index score to eliminate errors further. Finally, all levels of judgment matrix are acquired. Assignment method scaling are shown in Table 1:

Table 1 The linguistic description of the numerical scale in AHP

Scale	Definition	Explanation
1	Equal importance	Two activities considered equally important
3	Moderate importance of one over another	One activity is marginally favoured over another
5	Essential or strong importance	One activity is strongly favoured over another
7	Very strong importance	One activity is very strongly favoured and its dominance is demonstrated in practice
9	Extreme importance	The evidence favouring one activity over another is of the highest possible order
2,4,6,8		Intermediate values between two adjacent judgments

provides an estimation of the weight vector. The reliability of this estimation can be measured by the Consistency Ratio (CR): this measure indicates how consistent the comparisons are relative to large number of purely random judgements. Perfectly consistent judgments result in a consistency ratio of 0; CR=1 indicates that judgments were made randomly. As a general rule, a consistency ratio which does not exceed (0.10) is considered acceptable

2) Consistency test. In order to avoid the influence of other factors on the matrix, consistency test must be determined and the results can be analyzed. The calculation method on consistency for the judgment matrix is as follows:

$$CR = CI/CR \qquad (2)$$

The reliability of this estimation can be measured by the Consistency Ratio (CR). As a general rule, a consistency ratio which does not exceed (0.10) is considered acceptable,or we need to adjust the Elements of determine matrix.. *CI* is called Consistency Index. $CI=(\lambda_{max}-n)/(n-1)$, *Where λmax is the largest eigenvalue, n is the order of the matrix. RI is called* Random Index [4], shown as Table 2.

Table 2 Random Index

n	1	2	3	4	5	6	7
RI	0.00	0.00	0.58	0.90	1.12	1.24	1.32

After doing consistency test, based on the maximum eigenvalue λmax, the corresponding feature vector W is solved and W is normalized. Then the weights of alternatives, which reflect the relative importance of the attributes, are acquired.

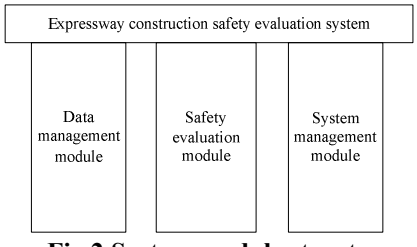

Fig 2 System module structure

Design of the evaluation system

Evaluation system function analysis

The expressway construction safety evaluation system adopts B/S structure and based on the database application system.The modular structure is shown in Fig 2.

The expressway construction safety evaluation system including data management module, safety evaluation module and system management module three modules.

(1)Data management module

The data include: system role authorization data, project attribute information, the construction unit, etc. The main function of this module is to complete a variety of data input, editing, storage, query, export, backup, etc.To prepare data for further safety evaluation, and complete the basic function such as output.

(2)Safety evaluation module

This module is the core module of the system, and can complete the safety evaluation on the selected object in human-computer interaction.Through analyzing the factors of safety performance, the evaluation units on-site status to get the production safety level and find the problems existing in the various units of production safety.Meanwhile, Sort the results of the safety evaluation and comparative analysis of the security situation of the construction unit. Provide scientific basis for safety management and decision-making.

(3)System management module

System management module provides the user rights management capabilities to ensure the security of the system data.

Evaluation system function design

The expressway construction safety evaluation system is an effective means to realize automation, construction site safety evaluation standardization, systematization [5]. Its main function is divided into two kinds: one kind is the data management, another kind is data analysis,as shown in Fig 3.

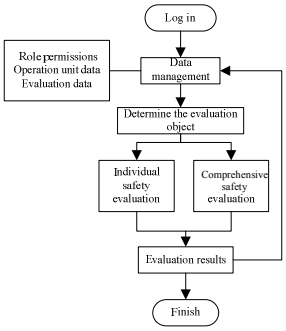

Fig 3 System function structure diagram

(1)Log in

In order to ensure the security of the system, the system implementation role to log in.The role is divided into seven categories, shown in table 3.

Table 3 Role Permissions

Attribution	Classification	Permissions
construction unit	System administrator	With full privileges
	Safety manager	Managing,inputting,editting,deleting and outputting the data of the construction unit; querying, statistics,and outputing the data of the operation units and supervision units.
	general staff	Browsing the data of the construction units
operation unit	Safety Manager	Managing,inputting,editting,deleting and outputting the data of operation unit;querying, statistics,and outputing the data of the operation units.
	general staff	Browsing the data of the operation units.
supervision unit	Safety manager	Managing,inputting,editting,deleting and outputting the data of supervision unit;querying, statistics,and outputing the data of the operation units.
	general staff	Browsing the data of the operation units.

(2) Data management

The data is the basis of the safety evaluation.The primary function of the system is to manage and maintain these data, including data input / output, storage, query, modify, and delete etc.

(3) Safety evaluation

Safety evaluation function of the system, including the individual safety evaluation and comprehensive safety evaluation of the operation unit.Rick evaluation is the core function of this system which is to analyze all the data, the calculation process.The system through the evaluation wizards in the project manager to guide step by step to complete the evaluation task.Its features include:

Create or query evaluation project.The system can create a new project evaluation and according to evaluation project name, evaluator or evaluation time to refer to the previous evaluation.

Defined scope of the evaluation, which means determine which construction units including the and evaluation content.

Get the evaluation result. The system can provide the evaluation object the level of safety and production safety problems, sort of production safety level of each evaluation object and comparative analysis of its security situation. Analysis results can be graphically intuitive description.

Instance apply

To verify the practicability of this evaluation system, we select a certain section of under construction expressway to study. First of all, through the expert evaluation, the security levels correspongding with the evaluation scores from 0 to 100. Specific corresponding standards as shown in table 4.

Table 4 Security levels corresponding table

Evaluation criteria	Security level	Actual situation
A≥90	V1 Very well	Construction safety situation is very well, the possibility of accident tends to zero
80≤A＜90	V2 Well	Construction safety situation is well, the possibility of accident is relatively small
70≤A＜80	V3 In general	Construction safety situation is ordinary,accidents may happen
60≤A＜70	V4 Bad	Construction safety situation is bad，the possibility of accident is great
A＜60	V5 Very bad	Construction safety situation is very bad, the possibility of accident is considerable

Using the Safety Check List and expert evaluation method to score for the all factors, score results as shown in table 5.

Table 5 Each evaluation index score table

Index	*A11*	*A12*	*A21*	*A22*	*A23*	*A24*	*A25*	*A26*	*A27*	*A31*
score	80	80	80	85	90	75	80	80	75	80
Index	*A32*	*A33*	*A34*	*A35*	*A36*	*A37*	*A41*	*A42*	*A43*	
score	75	85	70	80	80	85	80	70	75	

For the relative importance of each factor, there use the 1-9 scaling method to assign each index and at the same time structure Judgment Matrix at all levels. After passing through the consistency test, the weights of each index values as shown in table 6.

Table 6 All levels of index weight

Primary index / weight	*A1*/0.123			*A4*/0.101			
Secondary index / weight	*A11/0.753*		*A12/0.247*	*A41/0.176*		*A42/0.361*	*A43/0.463*
Primary index / weight	*A2/0.358*						
Secondary index / weight	*A21/0.253*	*A22/0.132*	*A23/0.127*	*A24/0.151*	*A25/0.154*	*A26/0.053*	*A27/0.130*
Primary index / weight	*A3/0.418*						
Secondary index/ weight	*A31/0.068*	*A32/0.085*	*A33/0.256*	*A34/0.266*	*A35/0.142*	*A36/0.088*	*A37/0.095*

After calculate the index weight of each secondary index can calculate the primary index scores,and then can calculate the score of the certain section of under construction expressway. After calculating, we can get the A1=80,A2=80.525,A3=78.67,A4 =74.075; the score of the certain section S=79.03. As the table 3 shows, the construction safety situation in this section is ordinary and accidents may happen. But through this data we know that the construction safety situation tends to be good.

Keywords: UML, Network Teaching, Interactive Platform

Abstract. Open network teaching is an important way of reforming and the trend of future development in the area of teaching, network interactive teaching platform is the key. This platform system is supported by network technology, relying on the campus network, effectively build an interactive learning environment with professional teachers, specialized courses and self-learning students. This paper mainly discussed the issues that how to use RUP and its iterative incremental development methods to carry out the object-oriented analysis, design and implementation; the detailed modeling techniques problems, such as how to use UML language to make the demand analysis and structural design for the platform system were also studied in this paper.

Introduction

UML (Unified Modeling Language) is a standard graphical Modeling Language, is also the third generation mechanism of industry standard, used for visualization, specification, construction and documentation of software system. UML can be put into use with all the development methods, life stages, application fields and media together, making the exchange of information in the software development process become more easily and convenient. Model (model) is purposive simplification for things, and provides a blueprint of the system. The basic reason for modeling is: because people can't understand a complex system completely, modeling is to make people have a better understanding of the system being developed.

This topic carries on researches aiming at a practical teaching reform project, and according to the law of education teaching, based on the discipline and specialty construction, giving full considerations to the characteristics of subject knowledge and the specific requirements of the teaching, it has studied how to use UML frame scientific and reasonable professional course network teaching system, design and build a common professional courses teaching website. The research and development not only has certain advancement in theory, at the same time has also reached the practical stage in the practical application. After some modification, it can get comprehensive promotion in each department and each professional as a general course teaching website.

Demand Analysis

Iterative incremental software development method. Object-oriented software development generally adopts the iterative incremental development process, this method is not disposable software submission at the end of the project, but block successive development and submission. Each iteration contains all of the stages of software life cycle, namely: analysis, design, implementation and testing phase [1]. As shown in Figure 2-1:

RUP development process. RUP defines requirements for "(under construction) the conditions system must conform to or the functions it must possess ". RUP is a test-driven, architecture-centric, iterative and incremental development process. The core characteristics of RUP is test-driven. The process of constructing test-model and user interface prototypes is an repeatedly iterative process,

which constantly interacts with the user in the iteration, and modifies the model and interface prototype according to the user's feedback information.

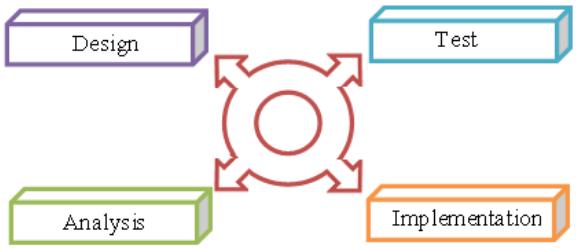

Figure 2-1 Iterative software development method

System Requirements.

1) Functional Requirements

The aim of teacher-student interaction platform system model, is to build a network teaching interaction platform for professional course teaching. The teaching platform construction should consider the characteristics of subject knowledge and the specific requirements of the subject teaching, based on subject construction. Therefore, the function requirements of the system mainly includes the following aspects:

Students can log platform modify personal information, ask questions online, online viewing and online testing.

- Students can login the platform to modify personal information, asking questions, viewing and testing on the Internet.
- Teachers can login the platform modify to personal information, answering questions, managing tests and courses on the Internet.
- System administrator can maintain pages, managing classes, teachers and curriculum provision.

2) Performance requirements

System model should have openness, high reliability, strong security and confidentiality [2].

Campus network platform for teachers and students mainly have three kinds of users: students, teachers and administrators, and different categories of users have different requirements on the function, efficiency, security and so on of the system. Platform system provides the following services:

1) Students and teachers access and use the system through the Web

2) Administrators can access and manage the system through the Web

The system should proceed the permissions distribution, the separation of land management and application for different roles, realizing the user registration, user login, user information changes, course management, test management and test, and other functions.

System Design

Any software design task can be shown as figure 3-1:

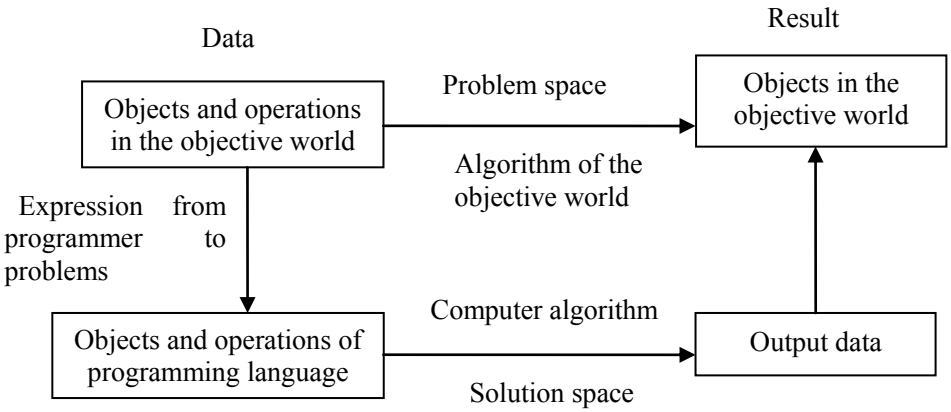

Figure 3-1 Typical model of system design task

In the problem space, problems are usually characterized by a set of objects of the objective world and operations on the object, and the task of the design is to transform these objects and operations of the objective world into an acceptable form for computer, namely in the solution space using programming language to express.The main task of object-oriented approach design phase is main parts design, user interface design, task management component design and data management component design. In software design phase, it needs further refinement for the demand, from the perspective of system implementation, with a model established in the requirements analysis stage as the input, which means to achieve all the requirements.

System function description.

1)System architecture

The core part of the site is a communication platform between teachers and students. According to functional requirements of the case and the definition of the system structure, functional architecture divided by professional courses teaching website is shown in figure 3-2 below:

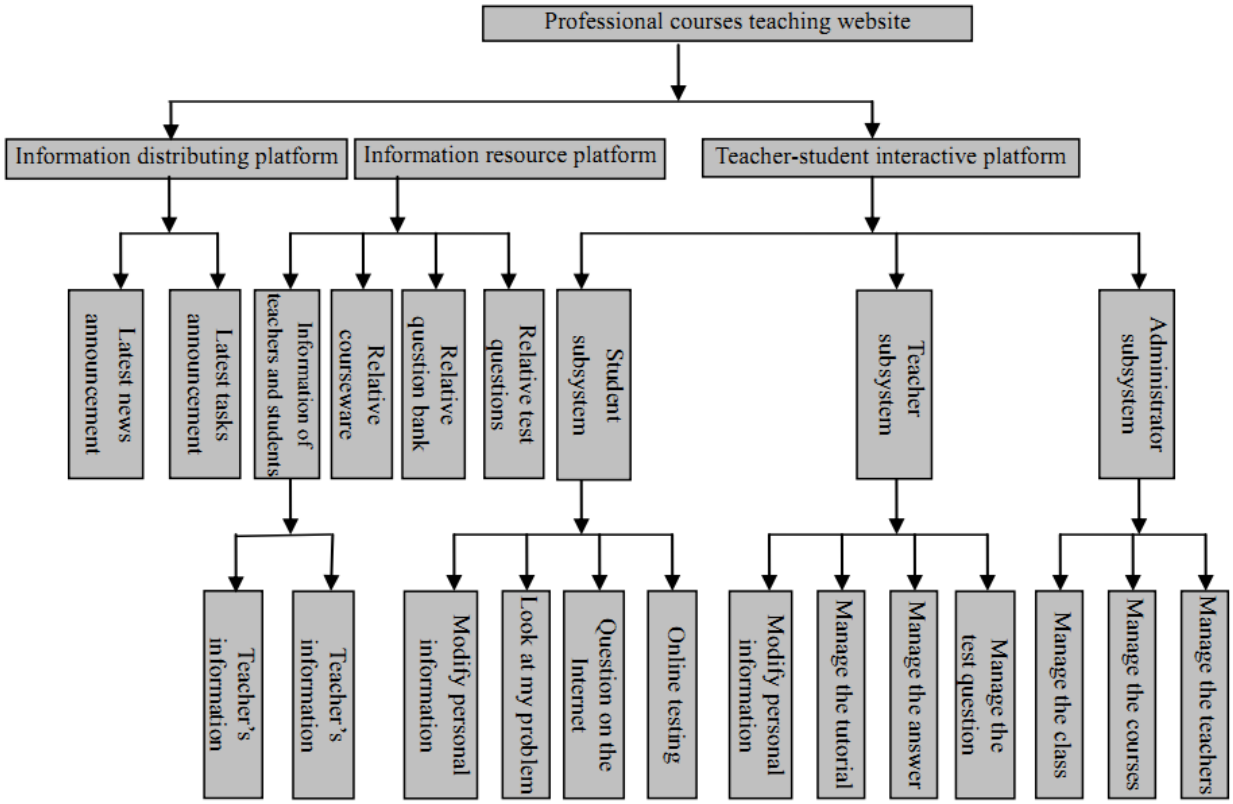

Figure 3-2 Site architecture diagram

2)User interface prototype design

The user interface is window of the system, and interface shapes the feeling of users on the system. Therefore, the design of the interface is in the primary position of human-computer interaction. The design of the interface follows the three important principles:

(1) under the control of the user

(2) reduce the user's memory load

(3) keep the consistency of the interface

System dynamic behavior model. State diagram is a model for the behavior of a single object, mainly observes state changes in the life cycle of the single object, including all of the states. The state diagram of the system is shown in Figure 3-3.

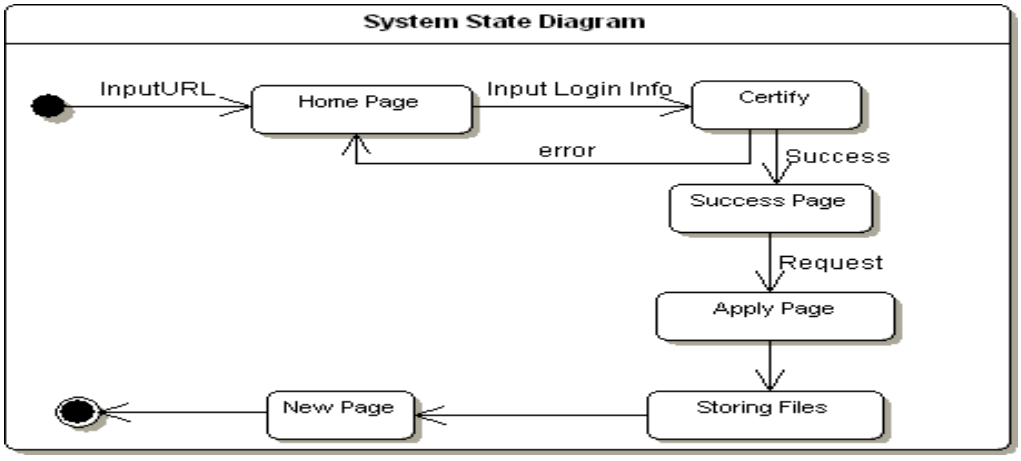

Figure 3-3System state figure

System static structure model. RUP is based on the object-oriented method, and in the requirements analysis phase its main task is to refine the demand requirements elicitation phase capturing. Firstly, extract each use case analysis classes, including boundary, control and entity classes; Then proceed implementation analysis for each use case according to the analysis classes, and analyzes the relationship between the classes, determine the class's attributes and methods; Finally, synthesize the analysis classes individual cases extracting to get the analysis class structure diagram of the whole system, so as to establish the static structure model[3].

System key technology.

1) Using ASP and its components technologies

2) Using software testing technology

3) Using UML modeling technology and RUP development technology

4) Using Web technology, and combining with ADO database programming interface and RDBMS technology

System implementation

System implementation.

1) System calculation mode

B/S mode client application software will be transplanted into the server, so the client will no longer need application program, through the browser to perform the application program. Its structure is shown in the following figure 4-1 [4].

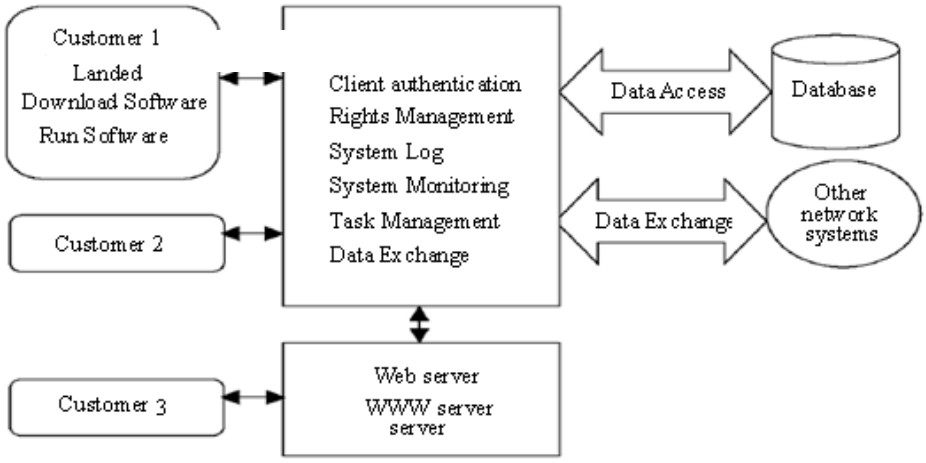

Figure 4-1 B/S structure mode

Logically, it is divided into four levels: client, Web server, application server and data server. The client is mainly responsible for human-computer interaction; The Web server is mainly responsible for the centralized management of the client application program. The application server is mainly responsible for centralized management of the application logic, namely transaction processing. In

the B/S structure, the size of the client has been compressed, and it becomes a simple browser. The application logic is centralized, located in one or more servers (application server).

2) Platform system logic model and component diagrams

a)Three-tier structure of teacher-student interaction platform system

According to the three-level structure theory, draw up system three-tier structure diagram, shown in Fig.4:

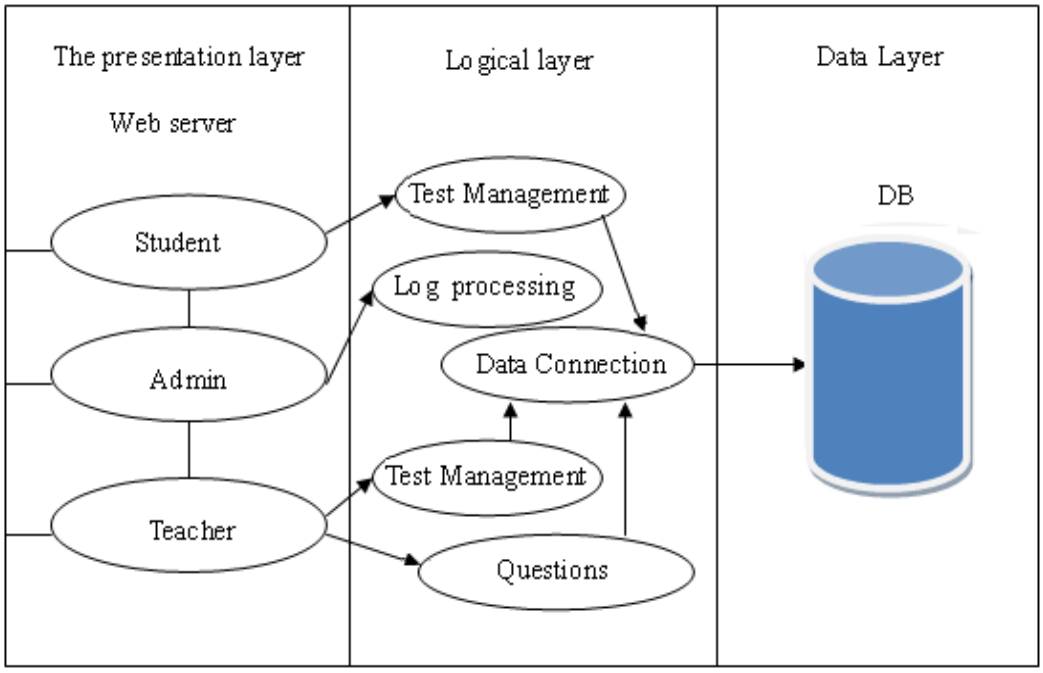

Figure 4-2 Three-tier structure of the system

(1) Presentation layer

System consists of three modules: the administrator module, students modules and teachers modules.

(2) Business layer

Business layer specifically defines the logic how to access information, namely how to define the SQL commands to access information.

(3) Data layer

Using ACCESS database as a backstage server, storing and managing persistent objects.

b) System component block diagram

The component diagram of the platform system is shown in figure 4-3.

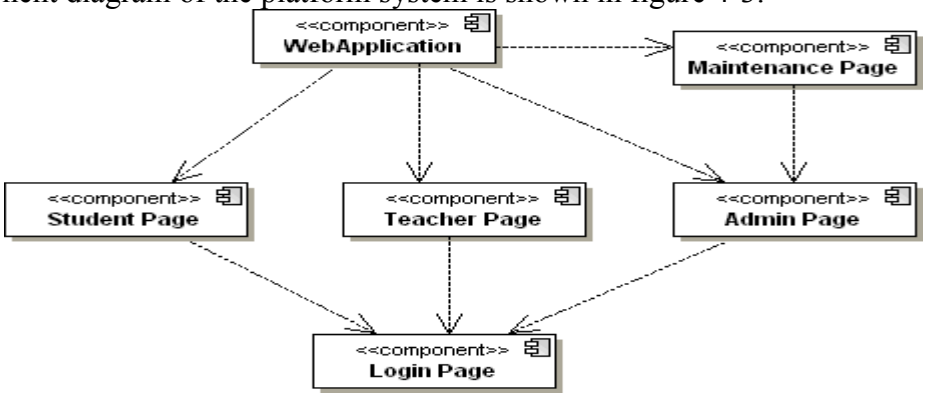

Figure 4-3 System component diagram

3) Physical model diagram and deployment diagram of the platform systems.

Deployment diagram is used to model for the physical aspects of object-oriented, establishing a visual model for physical nodes in the system model and static aspects of the relationship between the nodes[5].

From the three-tier structure model diagram, we can get the deployment diagram of the system model, as shown in figure 4-4: it has three nodes, "Web Server" and "DB Server" and "PC", peripherals "Printer".

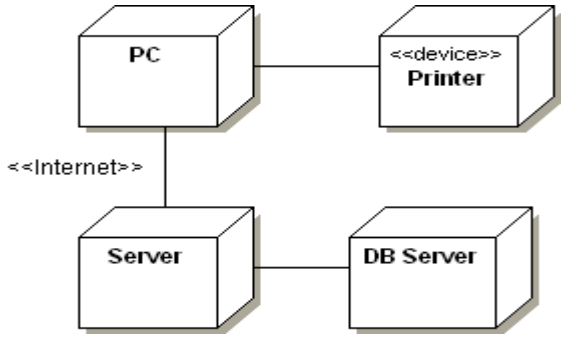

Figure 4-4System deployment

The system adopts B/S structure, using the Microsoft's 11 S architecture Web server, with the ACCESS as the database platform, and by using ASP technology, Web technology and database technology, has developed and designed the teacher-student interactive platform. Basic physical structure is shown in figure 4-5:

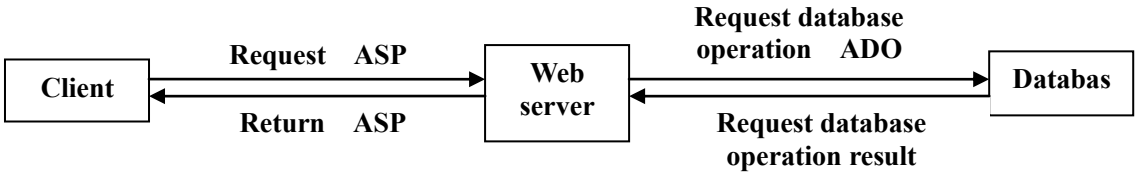

Figure 4-5 Basic structure of system

4)Platform system database implementation

The system uses Windows Access 2000 as the background database, and database is named CSTUDY.mdb. Database design refers to entity class diagram of the system design stage, the basic data collection of database, data structure and data processing flow should constitute a detailed data dictionary.

1) The design results of main tabular in the system database are shown in the figure below.

- Teacher table structure is shown in figure 4-6.

The Teacher table records the basic information of teachers registering, run by the administrator, and the teachers can modify the personal information.

teacher : 表

字段名称	数据类型
ID	自动编号
name	文本
age	文本
position	文本
photo	OLE 对象
or	数字
introduction	备注
IDname	文本
passwd	文本
email	文本
amount	数字
enroltime	日期/时间

Figure 4-6 Teacher table structure chart

tutorial : 表

字段名称	数据类型
ID	自动编号
rule	文本
title	文本
路径	文本
describe	文本
teacher	数字
refer	日期/时间

Figure 4-7 Tutorialtable structure chart

- Tutorial table structure is shown in figure 4-7.

The curriculum schedule records course name, path, the course description and the basic information of the course teachers, updated by the administrator.

2) Database connection

Using ADO database programming interface technology to connect.

System testing. Software testing is important for software quality assurance. After the discovery of errors by testing, diagnosis and correcting mistakes, to develop high quality software fully meeting the requirements of users. After the completion of the teacher-student interaction platform development, it need to review and test the designed webpage. On the one hand, through the establishment of a large number of test cases to test software. On the other hand, in the actual teaching, through constant interaction with students to verify and modify, thus ensuring the quality of the whole system.

Conclusion

Teacher-student interaction platform is a Web-based networked learning environment, which provides a networking platform of learning and working for teachers, students and administrators. Platform system adopts a hierarchical design structure, with Internet as the technical support, and the curriculum teaching for business support, realized the teaching interaction between professional teachers, curriculum and students on the true meaning. Due to the production work of the system is a system engineering and a long-term work, now it just build an online interactive system framework, establish and complete partial interaction function, compared with the teaching practice, its functions are relatively less and imperfect, which still need to be supplemented and improved in the future according to the actual teaching.

Keywords: Distribution Center; Distribution Model; Book Chain; Problems

Abstract. Coordinated and efficient distribution center is important for the standardization and modernization construction of chain operation for chain enterprise. As to book chain enterprises in China, it's a common issue for them as lacking of efficient distribution center and it's essential that every book chain enterprise have a scientific and rational managed distribution center. Therefore, the paper analyzed the status and problems of book chain enterprises in China while taking Xinhua Bookstore as an example, and proposed solving methods for them.

Introduction

As the bookstores owners often need to prepare a lot of book reserves to meet with the various needs of different groups [1], and they need to buy new books for the previous books will have few buyer after they have sold over a certain period of time, it's important for bookstores to have a high quality and speed of turnover. The distribution center combined of coordinated and efficient distribution system and information exchange systems is useful to ensure the quality and speed of resources turnover, and plays an important role in standardization and modernization construction of chain operation. Therefore, the ability to adapt to the establishment of distribution centers will determine the development of chain enterprises as well as its rise and decline.

Distribution center refers institutions and their facilities which receive and process ordering information from terminal users, sort various goods from upstream, fulfill picking, processing, distribution and other works according to user requirements, and deliver goods based on completed works[2]. That is they are organizations which get resources from its supplier with reasonable prices, require flip, classification, storage, distribution processing, information processing and other operations, and distribute required goods according to requires orders with their facilities and a satisfactory level of service.

Consumers have great differences in preferences for books and their selling time. To meet with the great differences, book stores often need to own many different books. As some books will have few buyers after they were sold some time later [3], its an important issue for bookstore to balance book varieties and book selling limitation. Thus, it requires bookstore owners to make right decision and make new books on selling as soon as they were published to meet with readers' requirement and requirement of high turnover of books. Also the outdated need to remove from the bookshelves as soon as possible and return to book publisher to decrease inventory costs [4], otherwise it will cause great increase in inventory costs. From the analysis above, we can see that distribution center is important for book sells, especially for book chain enterprises. The paper analyzed status, issues and solving methods of China book chain enterprises while taking Xinhua Bookstore as an example.

Status of Xinhua Bookstore Distribution Center

After a long specification and development, Xinhua Bookstore has been a book chain enterprise with many entity bookstores distributed in many cities from provinces to counties level allover China. Also, Xinhua Bookstore has been a worth choosing and trustworthy bookstore brand for its books reserves, involving disciplines, book quality and reader facing books, and so on.

For example, Wang is a purchaser of Xinhua Bookstore United Company Limited (Xinhua Bookstore Co. Ltd.). His daily works process is simple: first, login in Jiangxi Xinhua Bookstore website after input his user name and password; second, check the latest bibliographic of that day and the sales and inventory situation of various types books of its working bookstore and the headquarters; determine the book list of new books needed to buy and fill and confirm online orders; last, write down orders need to be confirmed. The headquarters will pick and distribute books required by orders from its sub-institution within 24 hours. Sometimes, Wang also drove four kilometers to exhibition hall of Chain Logistics Information Center in Nanchang Jingdong development Zone to pick sample books according to selling situation of his company, and input his requirement to ordering system which will send the information to the halls computer center and send books to Wang's working place within 24 hours.

This new distribution access is benefited from chain logistic distribution system of Jiangxi Xinhua Bookstore Co. Ltd (shorted as Jiangxi Xinhua Bookstore). running from September, 2003. Ordering information will be data exchanged through network video recorder screen software and logistics system software, and generate picking list automatically, and then be finished as picking and distribution operation completed under the conducted of electronic tag. This kind modern logistics distribution system makes Jiangxi Xinhua Bookstore has advantages facing to the new competition in the market.

The case above is only a better bookstore than other Xinhua Bookstores. In fact, there are Xinhua Bookstores still work under their traditional distribution system which can not meet with requirements of readers and the market, such as, selling books on the market demand can not be supplied timely and replenished; outdated can not be returned timely resulting sharp increase in the cost of inventory. The disadvantages of traditional distribution system of Xinhua Bookstores lead to little profit and bankrupting risk. Thus, a profitable distribution system is essential to Xinhua Bookstores to solve its market demand control problems and get profit from reasonable distribution system.

Distribution Model of Xinhua Bookstore

Concept of self-distribution model. Self-distribution model refers to a model that enterprises themselves build, organize, and manage all aspects of logistics and distribution business[5] to distribute internal and external goods for them. This model is conducive for enterprise to integrate its supply, production and sales operations. This model has a relatively high degree of systematization which can meet with the distribution needs of internal raw materials, semi-finished and finished products of the enterprise, also it meet the business needs to expand foreign markets. But, the distribution model will increase investment cost when establishing the distribution system, and will enhance distribution costs and expenses when the distribution scale of the enterprise is relatively smaller. Xinhua Bookstores chose this distribution model to distribute books by establish its own distribution system to complete enterprise distribution business, including the distribution and delivery of productions to enterprise internal and external customers for each sub-bookstore.

Xinhua Bookstore advantages under the self-distribution model. First, Xinhua Bookstore has a strong ability to control all aspects of its distribution. By using this model, it can plan reasonable management processes, improve the efficiency of logistics operations, reducing circulation costs. Self-logistics can make logistics and cash flow, information flow and business flow combine with each other closely, thereby improving logistics operations as well as a full range of work efficiency greatly. Second, it can make book purchasing, distribution, and production support the integration strategy to achieve timely book purchases, thus to increase purchases books batches, reduce its volumes, regulate inventory, reduce funds and reduce costs. Third, it can make the distribution of Xinhua Bookstore react fast and flexible by meet with time, space requirements in the logistics business and the more quickly and flexibly market requirements.

Disadvantages of Xinhua Bookstore with self-distribution model. First, the cost of investment to establish its own distribution system is high and the investment on it will increase operation cost.Second, the scale of self-distribution model often limited, and has lower specialization degree of

logistics and distribution compared with the distribution capacity of logistic enterprises, resulting to low distribution efficiency and increasing the difficulty of management control. Except that, the high logistics cost deduce the product competitiveness in the market and the limited scale of distribution system and low degree of logistics specialization can not meet with the increasing market needs.

Related Problems and Countermeasures for Book Distribution

Book distribution is a complex logistics process which similar to apparel industry in many respects. When new books launch, books may be on selling and short of supplying, but it can also become outdated goods within months as people turn their attention to update the books. For example, books write by some famous younger writer in China may short of supply in a month but date-out in a few months later which can illustrate this problem. Therefore, it's important to have enough reserves when a book on selling and return outdate books to suppliers to avoid inventory costs rise dramatically, giving a negative impact on corporate profits.

The main problems and resolution strategies to book chain distribution are shown as follows:

(1) The construction of distribution system for bookstore chain is lagging behind. The outstanding performance of this problem including three areas: the distribution scale is small; asymmetry information of many bookstore chains; backward technology and low distribution efficiency.

The solving strategies are: first, raise funds to build a logistics and distribution system with economies scale. With introduce of the advanced logistics technology and equipment, it can build modern warehouse, modern warehouse processes and automatic access and picking system.Second, strengthen the logistics infrastructure construction to form a scientific logistics network and to improve organization and networking degree of the construction of book chain distribution system which will perfect distribution information and improve the utilization of logistics resources.Third, promote the standardization of logistics technology, equipment and appliances. With the improving of logistic and distribution technologies, the operation efficiency of logistics and distribution will be improved. It can learn successful experience from distribution of chain enterprises at home and abroad to achieve scientific and rationalization construction of book chain logistics and distribution systems.By using a complete computer network system, distribution centers can achieve the integration of procurement[6], distribution and order processing, and can improve the accuracy of orders, efficient distribution and exchange of information to achieve scale management.

(2) Unreasonable site layout of distribution center. Faced with increasing global competition, companies have to increase its product quality, service levels and response speed to survive and develop in the market. Generally, logistics costs of a company is about 30 percent of its sales[7], thus, supply chain management is an effective way to reduce enterprise costs and an effective way to improve its efficiency. As the key component of the supply chain, distribution center determines the flow costs and supply chain efficiency [8]. Therefore, the location problem of distribution center is particularly important.

The solution is to design a rational distribution plan. The objectives of rational distribution includes: efficiently use space, equipment, personnel and energy resources ; minimize material handling; simplify processes; shorten the production cycle; seek investment minimum; provide convenient, comfortable, safe and healthy working environment for workers. Unscientific, irrational and unstandardized planning of logistics and distribution centers will result to low distribution efficiency, and result to increasing in waste and cost. Scientific and rational logistics center location and layout is very important.

Most chain bookstores still need to expand their scale; the outlets layout of these bookstores has not been locked. Thus, the site distribution center should be changeable to meet with changes of bookstore network, and the scale of distribution center should change according to the development of chain operation in order to have a rational planning of distribution centers construction, to reduce distribution costs and to improve chain efficiency.

(3) Lack of professionals on distribution management. To establish a logistics centers is to meet with the need of enterprises development, and the need of product to quick enter the market. But business executives is significant deficiencies in the experience and standardized management of

logistics and distribution, their basic concept of distribution has not changed, and their operations on logistics management and logistics technology is basically still stuck in the traditional job. What are worse, bookstores are unwilling to contribute to hire experts and practical aspects of logistics personnel to guide the construction and conduct training and education their staff. This may cause a problem that bookstores have modern distribution related facilities, but delivery and distribution management personnel is still under the traditional way of thinking which lead to the bookstore chains are lack of scientific distribution management.

To make modern bookstore chain have normal operation, modern logistics management software and professionals who use these logistics software. However, professionals in China's logistics industry are beyond the need. Therefore, we must make effort on the introduction of talent professionals; organize training programs to ensure the normal operation of the logistics center.

Summary

The unique diversified services of distribution center can relieve the burden on the business inventory adjustment, maintenance and other commodities of bookstore chain, which can improve the professional level of the retail book chain, to achieve the optimal combination of resources. Distribution center with high mechanization, high automation and advanced technical experience can protect the quality and distribution of goods to a great extent and effectively improve the efficiency of logistics, in order to achieve chain operation efficiency, conservation and high quality service. In short, the scientific rationalization distribution centers help to promote the development of book chain, increase its profits, and reduce inventory costs.

Keywords: Factors Breakeven analysis; Center of gravity method; Facility Location

Abstract. The so-called facility location means how to use scientific methods to determine the facility's location, so that the overall business operations and enterprise systems combine to effectively and economically achieve corporate business objectives. This paper introduces the Fuzhou Municipal Bureau of distribution center location tobacco case to be analyzed on the basis of this issue describes the significance of facility location, facility siting factors and principles are analyzed and siting of facilities the methods are summarized proposed general facility siting process steps, facility sitting decisions provide some guidance.

Introduction

A factory or service facilities should be set up where important decisions for the company is the design of business strategy. Especially in a large industrial facility siting, layout of the national economy of a country has a significant impact [1]. For an enterprise, facility location is the first step in the establishment and management of the enterprise is also the first step in expanding the business. The importance of facility siting is obvious importance mainly due to: facilities election after detachment facilities layout and production after the completion of the production and operation costs, and the cost of product and service quality has a great and lasting impact. Therefore, during the facility location must be fully taken into account many factors, careful decisions. Secondly, in addition to the new corporate facility location problem, with the development of differences in economic development, urban expansion, as well as between regions, many enterprises are facing the problem of relocation[2]. Thus, the facility location is a lot of companies are facing the modern enterprise management is an important issue.

In recent years, with the construction of the logistics industry to accelerate the pace to achieve low cost, high efficiency, excellent service distribution center is the target of the tobacco industry urgently front row. Thus, the location of distribution centers is essential.

Factors affecting the distribution center facility siting

This mainly refers to the stability of the regime of a country, whether legal sound, the existence of the trade embargo policy, as well as policies and regulations, finance, taxes and so on. China's economic development zones and industrial parks have policies.

Market conditions. Whether it is manufacturing or service location, facilities and customer must close and is the closer the better. Also, considering the demand for products and services area, the consumption level to adapt products and services and, if sales of the two close, transport costs will be reduced.

Resource conditions. Choose region should be considered the main raw materials, fuel, power, water and other resource conditions. In addition to material resources, but also give full consideration to human resources, the quality of workers of different products has different requirements.

Infrastructure. Trafficroads, telecommunications, and other infrastructure investments also have an impact on the establishment of the factory. Different sites have different costs spent. For my country, should try to use the land for farming is not suitable for siting of industrial facilities, not to take up agricultural land.

Competitors. In corporate location decisions must take into account the layout of competitors. Enterprises should be based on characteristics of the product or service itself, and to decide whether near or far away from rival competitors.

During facility siting, enterprises have influence factors are to be considered. In considering these factors, the needs to pay attention to are: first, we must carefully weigh these factors are listed, determine which is closely related with the facility location, though what the business or results of operations related. But the relationship with the facility location is not large, so that the decision is prioritizing, grab the key. Otherwise, too many factors listed sometimes easy to prioritize specific decisions could not tell at the time, can not make the best decisions. Second, under different circumstances, the same type of factors has influence. Therefore, any policy provision must not be applied mechanically, nor imitate copy existing experience. Finally, it should be noted that, for the manufacturing and non-manufacturing businesses, the impact and importance of the factors to be considered the same factors may be very different.

Distribution Center Location principles

Lot of success stories prove, on the siting, qualitative analysis is more important. Qualitative analysis is a prerequisite for quantitative analysis. In qualitative analysis, it is necessary to determine several principles.

Specific siting principles are as follows:

Cost principle. The first is the economic entity enterprise, economic benefits for business whenever and wherever they are important. Construction of the initial fixed costs, after running into variable expenses, product revenue after the sale, is related with the site.

The principle of aggregation of talent. Talent is the most valuable resource[3]; business address election was conducive to attracting the right talent. Conversely, due to corporate relocation inconvenience caused by the staff of life, the facts that staff turnover often occur.

Close to the user principle. For the service sector, almost without exception, are required to follow this principle, such as savings banks, post offices, cinemas, hospitals, schools, retail stores, etc. all. Many manufacturing companies have built their factories near the consumer market, in order to reduce shipping costs and losses.

The principle of long-term development. Business location is a strategic management activities with, so to have strategic awareness. Site work should take into account the rational distribution of productive enterprise, to consider the market development; access to new technologies should be conducive to new ideas. In the current world economic integration become more and more background, to consider how conducive to participate in international competition.

Locating

Factor score. Common factors in the siting scoring method is perhaps the most widely used one[4], because it will be easy to understand patterns of different factors together. Specific steps factor scoring method is as follows: Determine a set of factors related to siting decisions; for each assigned a weighting factor to reflect the importance of this factor in the ownership of weight. Value of each factor is determined according to the weight, and the weight will have a cost according to the determined standard deviation, rather than the cost value is determined; scoring of all the factors of a common set ranges, usually 1-10 or 1-100; for each alternative addresses for all of the factors set range by scoring; Score multiplied by the corresponding weight of the weight of each factor, and the value of all the weighting factors are added to obtain the address of each alternative final score. Select the address with the highest total score as the best location.

Using this method should be noted: The use of factor score in the calculation process can be found, because the right to determine the number and grade score relies entirely on people's subjective judgment, as long as the error of judgment will affect the numerical score, the final impact on the likelihood of decisions. There are a lot number to determine the right approach is more objective and accurate method the Analytic Hierarchy Process(AHP) [5].The method is not complicated, there is a

more rigorous scientific basis, we recommend the program to do more when using AHP as multi-factor evaluation.

Breakeven analysis.Profit and loss analysis is a basic method of plant siting, also known quantity-benefit analysis [6]. This method is based on the following assumptions: Various options available can meet the basic requirements of site selection, but the amount of investment for each program is different, different changes in raw material costs, fuel, power and other future production. Then, you can use the principles of breakeven analysis to the level of production costs as compared to the production standards. The basic steps are as follows: Determine the fixed and variable costs of each option; make different programs cost income curve; determined at a predetermined production or sales, the lowest cost or profit in accordance with the highest principles select a best solution.

Center of gravity method. Center of gravity method is a method of individual facilities layout [7]; this approach should consider the distance between the existing facilities and the amount of cargo to be transported. It is often used for the intermediate storage of the selection. In the simplest case, this method assumes that the incoming and the costs are equal, it is not considered in the full load condition without increasing the cost of special transportation.

Center of gravity method first bid at the location coordinates of each site; the purpose is to determine the relative distance between each point. Coordinate system can easily be established. Then, the value of the transport position is obtained at the lowest cost according to the coordinates X and Y in the horizontal and vertical coordinates of each point in the coordinate system.

Comprehensive evaluation method. Gravity method and breakeven analysis is a quantitative method. But in real life, there are some non-facility locations factors beyond quantitative analysis with quantitative model area, various factors must be taken into account in order to make the right decisions.

Delphi analysis model. Some location analysis involving multiple facilities and multiple targets, its decision-making is relatively vague goals, and even emotionally. One way to solve this problem is to use the Delphi site analysis model. The model takes into account various factors in the decision-making process. Use Delphi analysis model involves three groups, namely coordination group, team and strategic forecasting group[8]. Each team plays a different role in decision-making. To use this model as follows:

(1) The establishment of two groups. Internal and external personnel consultant closed, acting as coordinator, responsible for designing the questionnaire and guidance Delphi survey. Some of the people elected advisory group set up two groups. A team responsible for forecasting and social trends and the factors that affect the organization of the external environment test. Another group determines the organization's strategic objectives and priorities (Strategy Group). Members of the team from the company strategy in the selection of senior managers

(2) Identify threats and opportunities exist. After several rounds of questionnaires, coordinating group should be asked to forecast the development trend of social groups, market opportunities and threats facing the organization. This stage, should listen to the views of the majority as far as possible.

(3) Identify strategic objectives and strategic direction of the organization. The coordination group findings back to the group's strategic forecasting group. Strategy team used this information to determine the strategic direction and strategic objectives of the organization.

(4) Make alternative. Once the team identified long-term strategic objectives, it should focus on the various options proposed. (Alternative party is the expansion of the existing plant facilities or compression and for all or part of the plant's location change).

(5) Optimization options. Step 4 alternatives proposed in the strategy group should be submitted to the relevant personnel to get their subjective evaluation of programs.

(6) In considering the strengths and weaknesses of the organization on the basis of the model can identify trends and opportunities in the organization. In addition, the model also takes into account the company's strategic objectives, in the modern corporation as a typical comprehensive group decision making method is widely used.

Summary

Facility location is an issue of economic politics, culture and technology intersect, with the advance wave of economic globalization to the globalization of production; capital is characterized by globalization and the globalization of markets. Site occupies the entire logistics system is very important for the low, are research questions of logistics management strategic level, it is a single enterprise, which determines the level of the entire logistics system, and other structures, plays an important role in enterprise management, effectively do site work, far-reaching impact on the development of enterprises.

Study on Classification of body shape and Size Grading on Young Women of Quanzhou District

Can-yi Huang[1,a]

[1]Deparment of Business and Information, Quanzhou Normal University, Quanzhou, Fujian, 362000, P.R. China;

[a]email:yidyj126@sina.com

Keywords: young women; classification of body shape; size standard; data grading

Abstract. Body measurement was carried out on 500 young women, who come from Quanzhou district, and we also utilized SPSS software to carry on statistic analysis to the samples, 13 measuring body variables were chosen and 11derived variables were calculated. Then classification analysis was used to classify the body shape .Then this paper subdivided the upper body of young woman's body shape into 4 kinds, the lower body into 4 kinds also .Finally, values of intermediate of every type and stepping number values of every measurement are calculated through regression analysis.So the database of classification of body shape and data of young woman was obtained.

Introduction

Nowadays, apparel's fitness has been widely considered as an important indicator affecting clothing's appearance and comfort. The intention of body shape classification is providing the basis for the clothing's style and structure design, and it will greatly affect the fitness of clothing products [1]. Our country is still using the old national standard of garment size; body data of this standard come from last century 90's anthropometric data. However, the standard now can not truly reflect the characteristics of somatotype in china. Therefore, it is necessary to improve the standard of garment size by using more reasonable shape classification method [2].

Body measurement experiment

In the experiment, 500 Quanzhou female university students at the age of 18~ 22 are measured. This study uses the manual measurement method, in order to make the scale unified and data accurate, special groups of measurers are designated to take the measurement experiment. Testees all wore thin underwear, remain stationary and natural upright when measuring. Martin measuring instrument s and measuring reels are used in the manual measurement.

This study selected 13 human representative measurement parts, which can cover all main control parts of the whole body. They were: height, chest circumference, waist circumference, hip circumference, shoulder width, neck circumference, front waist length, back waist length, upper body length, lower body length, chest horizontal length, hip horizontal length and hip height.

Analysis of body shape clustering

In current national standard of apparel size, the human body shapes are divided into 4 categories. And the standard can not really reflect the size differences between human bodies[3]. Meanwhile we try to divide human shape more in detail, so this study attempts to classify the upper and lower human body separately. This research takes derived variables which can reflect human body's horizontal and vertical changes and other relevant variables as the reference index for body shape's classification. These derived variables are calculated through important controlling parts of the body. These derived variables are shown in table 1.

Tab. 1 Each derived variable and definition

derived variables	definition	derived variables	definition
R1	chest circumference - waist circumference	R7	hip circumference - waist circumference
R2	chest circumference / waist circumference	R8	hip circumference / waist circumference
R3	upper body length / chest horizontal length	R9	lower body length / hip horizontal length
R4	front waist length – back waist length	R10	lower body length / hip circumference
R5	upper body length / chest circumference	R11	lower body length / waist circumference
R6	upper body length / waist circumference		

3.1 The body shape cluster analysis

Using single factor variance analysis through SPSS statistical software, each derived variables of the upper body is inspected and analyzed separately with the key parts of upper body，upper body length, chest circumference and waist circumference. Table 2 shows F value and significance level of the single factor analysis of variance. Synthesis results show that: the variable R3 is significant with chest circumference and waist circumference [4], and close to be significant with upper body length, significant effect is better than the other four indicators; the variable R5 is significant with the upper body and waist circumference, and close to be significant with chest circumference. So this research takes these 2 variables as indicators to cluster analysis. Table 3 gives the K-MEANS cluster analysis, the index terminate clustering center and sample proportion when samples are divided into 3, 4, 5, 6 kinds. After comparing the results when samples are divided into different categories, we find out that the result that samples are divided into 4 categories, difference between each two categories show adjacent to clear and uniform. So the young female body shape is divided into 4 categories. They are indicated with A, B, C, D.

By using the same method with upper body, the synthesis results show the significant effect of R9 and R8 are better than the other four indicators, so take these 2 variables as indicators for clustering analysis. And the young female lower body shape is divided into 4 categories. They are indicated with W, X, Y, Z, and the classification results are in table 4.

Tab. 2 Onaway anova between each derived variable and the key part of upper body

	parts	R3	R4	R1	R2	R6	R5
F value	upper body length	1.295	2.020	0.995	1.116	1.992	3.068
	chest circumference	3.573	0.782	1.449	3.972	3.416	1.369
	waist circumference	2.827	0.862	1.005	4.977	1.069	3.865
significance level	upper body length	0.058	0.001	0.506	0.549	0.002	0.000
	chest circumference	0.002	0.846	0.055	0.001	0.003	0.019
	waist circumference	0.004	0.730	0.490	0.000	0.386	0.000

Tab. 3 Final cluster center of K-MEANS and sample ratio (upper body)

Category	R3/R5	Ratio	Category	R3/R5	Ratio	Category	R3/R5	Ratio	Category	R3/R5	Ratio
1	1.05/0.53	34.0%	1	1.03/0.52	17.4%	1	0.9/0.42	0.60%	1	0.89/0.41	0.50%
2	1.18/0.57	46.7%	2	1.11/0.56	26.4%	2	1.04/0.52	25.3%	2	1.04/0.52	22.1%
3	1.26/0.63	19.3%	3	1.19/0.59	37.6%	3	1.11/0.57	24.6%	3	1.16/0.56	23.3%
			4	1.27/0.63	18.6%	4	1.18/0.59	32.7%	4	1.09/0.57	20.0%
						5	1.27/0.63	16.7%	5	1.19/0.62	22.0%
									6	1.28/0.62	12.1%

Tab. 4 Cluster result of body type

Category	R3	R5	Sample number	Category	R9	R8	Sample number
A	1.03	0.52	87	W	2.78	1.31	106
B	1.11	0.56	132	X	2.92	1.33	150
C	1.19	0.59	188	Y	3.03	1.36	167
D	1.27	0.63	93	Z	3.21	1.38	77

Determination of intermediate type values and stepping values of each measurement parts

4.1 Determination of intermediate type values of each measurement parts

Filtering out sample body with each figure types of the upper and lower body, we can obtain 7 data files. Take the mean values of anthropometric data as the final values intermediates body type, for the consideration of the convenience of data application, some simplifications were done to the data, the results are in Table 5 and table 6.

Tab. 5 Reduced measurement data of intermediate type of upper body cm

categaory	Upper body length	Chest circumference	Waist circumference	Shoulder width	Neck circumference	Chest horizontal length
A	37.5	84.0	68.5	39.0	33.5	34.5
B	38.0	82.0	66.0	38.5	33.0	33.5
C	39	81.5	65.0	38.0	32.5	32.5
D	39.5	80.0	63.0	37.5	32.0	31.0

Tab. 6 Reduced measurement data of intermediate type of lower body cm

categaory	Lower body length	Waist cicumference	Hip cicumference	Hip horizontal length	hip height
W	96.5	69.5	93.0	35	20.5
X	98.5	67.0	90.5	34	21.5
Y	101.0	64.5	88.0	33	22.5
Z	103.0	62.0	85.0	32	23.5

4. 2 Determination of stepping values of each body shape

In this research, the stepping number of the three basic control of parts of the body (body height, chest and waist) will be smaller than the current standard of 5 • 4 series, we consider 2.5• 2 series. So, values of each measurement parts can be calculated by simple or duality linear regression with body height and chest circumference, mathematical model of regression is: $y = \alpha x1 + \beta x2 + \gamma$. So as long as we get the stepping values of basic parts of human body,we can calculate each measurement parts' stepping values [5].So, the stepping values of each part= α *stepping values of height+ β *stepping value of chest。Results are simplified as shown in table 7.

Tab. 7 Stepping values of measured parts of upper and lower body cm

measured parts	Stepping value				measured parts	Stepping value			
	A	B	C	D		W	X	Y	Z
Upper body length	0.60	0.50	0.50	0.60	Lower body length	1.7	1.8	1.9	2.0
Chest circumference	2.0	2.0	2.0	2.0	Waist circumference	2.0	2.0	2.0	2.0

Waist circumference	2.0	2.0	2.0	2.0	Hip cicumference	2.0	1.9	1.8	1.7
Shoulder width	0.7	0.8	0.8	0.7	Hip horizontal length	0.8	0.8	0.7	0.7
Neck cicumference	1.1	1.0	1.1	1.0	Hip height	0.4	0.4	0.4	0.5
Chest horizontal length	0.50	0.50	0.50	0.60					

Conclusion

Using SPSS statistical analysis software to analyze the measuring data, through the single factor analysis of variance, upper and lower body indexes were obtained, and further through K-MEANS quick cluster, the youth female upper and lower body are divided into 4 categories respectively, Finally, the stepping value and intermediate type values can provide a powerful data support for young woman's clothing production enterprises whose target customer group is Quanzhou area.

Key word: the waterfront, post evaluation, system dynamics

Abstract. City waterfront landscape project post assessment research is still at the starting stage in our country, the related system research is very few. There are still many shortcomings of the original evaluation, it need to improve, the system dynamics makes up the deficiency in many respects. We can evaluate and analyse the city waterfront landscape by using hybrid evaluation method of the method of system dynamics. Construct the post assessment of waterfront landscape suit to the situation of our country.

Introduction

Water gives birth to life, waterfront gave birth to the city and city culture, is an important part of city development. Waterfront landscape occupies an important position in the city landscape. With the rapid development of the city today, People on all aspects of the requirements in gradually enhancement. The better Waterfront landscape not only has its aesthetic value, but also develop its ecological function, To promote the development of the city. Therefore, according to the relationship between the city and the waterfront landscape development as a starting point for research, discussion and evaluation on the waterfront landscape, In the future, it is good for us to contribute to the planning of waterfront landscape.

Post Assessment has many methods can evaluate city waterfront landscape

Contrast method. Evaluate the waterfront landscape by using contrast method. First of all, starting from the change before and after a waterfront landscape construction, find out the reasons for the changes, comparison of the effect of the waterfront landscape of city, people, environment effectively. In addition, from the point of view of with and without, judge City waterfront landscape has effect to the city development, and evaluate the waterfront landscape.

Statistical forecast method. Evaluate the waterfront landscape with the statistical forecast method, before the construction of waterfront landscape，based on statistics，using the quantitative prediction methods, evaluate the project. This method needs to collect some information, including the area's ecological environment, traffic conditions, flow of people, and the people hold the construction of waterfront landscape attitude etc. Test prediction method is applicable, and determine the predictive value ultimately.

Logical framework approach. Evaluate the waterfront landscape by using logical framework approach, this is a method of discuss project, use this method to evaluate the waterfront landscape, the project must be given a clear definition. Through establish logical framework, evaluate the city waterfront landscape.

The analytic hierarchy process. We can use the analytic hierarchy process to evaluate thewaterfront landscape, construct of a city waterfront landscape，there are N targets，Each target analyse independently, and each target can influence other targets through any factor. Through hierarchy analysis, evaluate the city waterfront landscape.

Causal analysis. We can use the causal analysis to evaluate the waterfront landscape, After the completion of the construction is still having the funds to maintain its stability, it can be considered

as a long-term project. Analysing the engineering before and after construction. We can analyse the largest influence of the waterfront landscape, and find the crux of the problems, through the in-depth research and drawing the causality diagram, analyse the causality diagram, and evaluate the city waterfront landscape.

Comprehensive evaluation. We can use the comprehensive evaluation to evaluate the waterfront landscape, the Post evaluation needs to analyze the project economic effect, environment effect, social effect, evaluate the project synthetically.

Success assessment. We can use the success assessment to evaluate the waterfront landscape, rely on the rich experience of experts and expert groups, evaluate the project objective synthetically. According to the degree of success criteria, evaluate the project. Evaluate the waterfront landscape base on the evaluation method of grey theory, relate to the degree of a number of different indicators and projects based on many experts, establish the mathematical relationships and analysis, evaluate the project synthetically.

Research Status

The Research of city waterfront landscape post assessment is still at an early stage, the Research of complete system are very few. Yue Liang used the fuzzy comprehensive analysis method to evaluate the city waterfront landscape, it contained landscape, ecological evaluation, social evaluation, economic evaluation et, the landscape evaluation involves many elements, the secondary factor has no clear boundary, according to the two levels of evaluation elements and factors in the system, present two level fuzzy comprehensive evaluation. Zhu Jianhong used the method of fuzzy mathematics to establish a mathematical evaluation model, evaluate the city waterfront landscape, provide decision basis for the design and construction of the waterfront landscape[1]. Zhu Runyu use the simulate evaluative method as a guide, take Nanjing Mochou Lake as an example evaluate the landscape, and get the important factors which influence the quality of the waterfront landscape, it is help for the future planning and design. Huang Guoping use the fuzzy mathematics to establish the matrix model, solve the fuzzy matrix and obtain all the factors weight coefficient of the waterfront landscape, it can guide the planning and design of the city water landscape.

System dynamics is used in various types of system

System dynamics is used in assessment of tourism planning. Xu Honggang used the theory and principle of the **sys**tem dynamics to plan tourism. Usd the principle and method of the **sys**tem dynamics in the tourism planning, make analysis of tourism planning of Guilim. Its contents include the determination of the reference mode, a lot of feedback analysis and process analysis, establish the relevant feedback and planning graph, and discuss the significance of system dynamics in tourism planning[2].

System dynamics is used in the agricultural ecological environment evaluation. Tang Jie make Jilin Daan as an example, according to various characteristics of agricultural ecological environment, usd the principle and method of the **sys**tem dynamics to establish the simulation model of the system dynamics, Studied on the ecological environment planning simulation, and find out the best scheme suitable for economic development[3].

System dynamics is used in evaluation of sustainable development. Zhang Aisheng presented the system dynamics was applied to regional sustainable development research, presented the regional resources development and ecological balance as the core to plan and research, pointed out the key directions for future research on Sustainable Development[4].

System dynamics is used in the health evaluation of water system. Huang Guoru Researched on the evaluation index system of water system health. First of all, used AHP to get the weight of each index, according to the method of system dynamics to build water system health evaluative model, collected some related materials, used the system dynamics to simulate the health water system next few years, through feedback regulation of each index, Can promote the stable, healthy development of water-based system[5].

System dynamics is used in city waterfront landscape post assessment.

The post assessment system of the city waterfront landscape sustainable development is an important part of the system of the city waterfront landscape post assessment. The system of the city waterfront landscape post assessment is showed on figure 1, the effect of post evaluation system contains several main indexes. It includs the water ecological environment sustainable index, construction and maintenance of sustainable index, social and economic development policies and sustainable management index, each indicator consists of a number of factors, each factor is divided into several secondary influence factors. The multiple effect factors can be used to analyze and evaluate rely on the system dynamics.

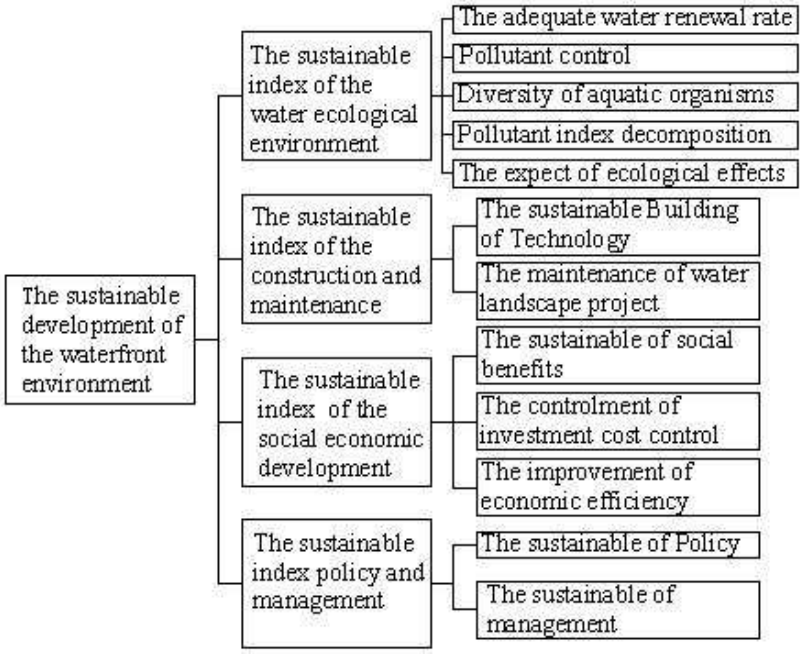

Figure 1

The system dynamics is a discipline which includes study and analysis of information feedback system, according to the feedback among the various factors affecting the waterfront ecological function, aesthetic value, economic benefit, evaluate the waterfront environment synthetically.

The ecological environment of causal feedback diagram is showed on figure 2, it can reflect the relationship between the waterfront ecological system of sustainable development and the influence factors simply. According to the feedback causality diagram, evaluate waterfront environment ecosystem sustainable development.

The figure present The relationship between the waterfront ecological system of sustainable development and the influence factors, according to the feedback causality diagram evaluate waterfront environment ecosystem sustainable development. The typical positive feedback and negative feedback loop is shown as follows.

(1)The ecological environment of the waters $\xrightarrow{+}$ The quality of the landscape $\xrightarrow{+}$ The flowrate of people $\xrightarrow{+}$ Landscape visibility $\xrightarrow{+}$ Capital investment $\xrightarrow{+}$ The ecological environment of the waters.

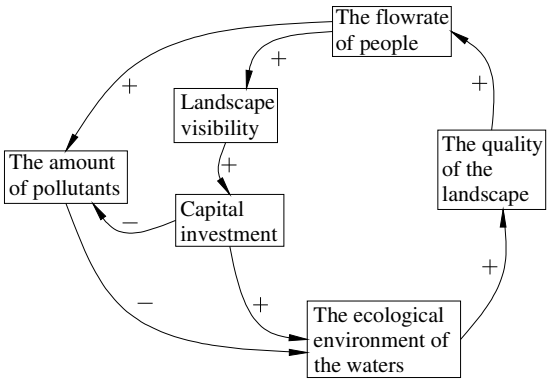

Figure 2

(2) The ecological environment of the waters $\xrightarrow{+}$ The quality of the landscape $\xrightarrow{+}$ The flowrate of people $\xrightarrow{+}$ The amount of pollutants $\xrightarrow{-}$ The ecological environment of the waters.

Rely on analysis on causal loop system, establish the system dynamics model of the city waterfront landscape to analysis the whole system.

Summary

At present, many method rely on establish the fuzzy mathematical model to Analyse and evaluate the city waterfront landscape, and guide the design of waterfront landscape. Used hybrid evaluation method which includes system dynamics, combined with computer simulation technology, detection and repair technology of environmental engineering, Outstanding landscape user participation, accessibility and fairness. Present the effect post assessment of the city waterfront landscape, the effect post assessment of the landscape, the post assessment of the sustainable development, guide the waterfront landscape design well. System dynamics is suitable for the study of complex systems, it is suitable for processing some problem which require long period and insufficient data. Although the history of its development is relatively short, but its method system is continuously improved, the correct guidance system design, represent the full range of value.

The modeling of buildings cost assessment expert system with differences

Yin haiwen

Pingxiang University, Pingxiang Jiangxi 337000, China

Keywords: hybrid construction; costs assessment model; multi-cost information constrains

Abstract: It's difficult to estimate the costs of hybrid constructions with great differentiations. This paper proposes a hybrid construction costs optimization model by reasonably selecting the feature attributes during costs estimation. SVR prediction model is established and it's trained to shape the analog hybrid construction cost information estimation model. The experimental results show that the proposed model can accurately predicate the hybrid construction costs with higher efficiency.

1 Introduction

It's important for the construction management personnel effectively estimates and controls the construction costs which will allow them provide optimal construction costs schemes to reduce the costs and maximize the profits. Each building has its own characteristics and there are common characteristics associated with different buildings. The analysis of the similarity of these characteristics can effectively estimate the costs of the hybrid constructions [1,2]. It's difficult to estimate specific costs of the hybrid construction due to the impact factors are variable and complicated. Only the probability of the costs in some specific range can be estimated. Therefore, it's important to search effective construction costs estimation method [3,4]. It's research focus for accurately estimate hybrid construction costs in current construction cost analysis area. With the increase of the constrains for the construction costs, the amounts and characteristics of the building are diversified. The traditional BP neural network estimation method cannot be used for the cost-oriented hybrid construction cost estimation issue because it cannot build the effective convergence assessment model and cannot get accurate costs estimation results.

2 The project cost assessment model

2.1 The selection of the feature attributes

In the project establishment phases, the project features refer to the characteristics that mostly impact the project costs. Therefore, it's important to select the project features while using SVR to estimate the project costs. There are two main principles in this paper for selecting the project features- "fine" and "difference." "Fine" refers to the selected project features must have a greater impact on the costs. Obviously, there is no practical significance for selecting the features with little impacts on the project costs; "difference" refers to that the selected features should show the differences because if all the features are the same they cannot be distinguished by SVR model and have no contributions for the prediction results.

Because the above reasons and the brick structure residual buildings are considered, 6 attributes-building area, basic form, layers, structure types, maximum opening, and amounts of windows and doors, are used as the project estimation features.

2.2 The establishment of SVR prediction model

This paper applies Libsvem-3.1 toolbox to build SVR predication model and the detailed steps are as follows.

1）Data normalization

In order to make the attributes comparable, they are normalized by equation (1).

$$y = (x - x_{\min}) / (x_{\max} - x_{\min}) \quad (1)$$

In the equation, x,y$\in R^n$, n denotes the amount of attributes, x_{min}=min(x), x_{max}=max(x). The purpose of the data normalization is to map the original data to the range of [0,1] to make them comparable.

2）The selection of core functions

The types of the core functions in the Support Vector Machine are directly related with the regression results. The performance of SVR based on Radial Basic Functions (RBF) is much better that those with other core functions. Therefore, RBF in the proposed SVR model should be carefully selected.

3）The determination of optimal parameters

SVR has two parameters which are regularization parameters *c* in objective function and the parameter *g* in the core function. Because they impact the predication performance of SVR to large extent, the parameters should be optimized.

The K-fold Cross Validation (K-CV）method is used to search the optimal parameters whose principles are gradually adjusting the parameters of c and g to minimize the predication Mean Squared Errors (MSE). Finally, the optimal value is c=256，g=0.0068012 and MSE=0.023229.

2.3 The training and predication of the model

This paper selects the data from 14 residential buildings as the training samples. Artificial Neural Network (ANN) and SVR are used to build the prediction models respectively. The data of A15 is used to testify the correctness of the two models and the experimental results are shown in Table 1.

Table 1 The predication results based on SVR and ANN project cost assessment models

No. of the building	The actual cost	SVR predication value	SVR relative errors	ANN predication value	ANN relative error
A15	1.08125	1.08442	0.0029	0.94674	-0.1244

In the Table 1, the fitting results of SVR model is very satisfactory and the relative error is 0.29% which is less than 1%. Compared with ANN model, the relative errors of SVR is 0.29% which is obviously less than those of 12.44% in ANN model. The results illustrate the predication performance of SVR model is better than ANN model.

In this case, it's reasonable that the predication effects of SVR model are better than ANN model. For one aspect, the design of SVR model considers the fitting and generalization of the test samples, while ANN model only considers the fitting of the data; for another aspect, ANN model is usually applied in large scale of data and SVR model focuses on small scale of data. There are only 14 training samples in this experiments which is typical small scale of data. In summary, SVR model is better for project assessment model than ANN model.

3 Experiments and simulations

3.1 The source of the experimental data

The experiments are used to test the proposed hybrid construction costs assessment model based on multi-cost information reasonable constrains. The experiment selects 10 groups of data of different types of hybrid residential constructions from the *hybrid construction costs* of some city from 2008 to 2011.

These data are preprocessed and 8 features of the average construction areas, average number of floors, average height of each floor, flat shape, structure type, base type, bearing capacity, and depth from different types of hybrid constructions are selected as the relative hybrid construction costs features and the specific data are described in Table 1.

3.2 The hybrid construction cost assessment

In order to verify the validity of the proposed model for hybrid construction costs assessment, the proposed model and traditional BP neural network model are used to evaluate the costs of different types of hybrid construction in Table 2. The structure of BP neural network is 10*22*2. The detailed hybrid construction costs are described in Table 2.

Table 2 The assessment results of the proposed model and the traditional BP neural network model

	The hybrid construction costs（yuan·m^{-2}）				
Models	18	19	20	21	22
Actual cost	1476.6	1409.8	1424.6	1378.9	1349.0
Proposed model	1469.7	1488.7	1419.5	1367.4	1336.8
BP neural network model	1587.9	1577.9	1564.9	1451.6	1400.8

In order to prove the advantages of the proposed model, The Mean Squared Errors (MSE) and Mean Absolute Percentage Errors (MAPE) of the proposed model and BP neural network model are compared by combining Table 2. MSE and MAPE are expressed by

$$MSE = \frac{\sum (y_i - \hat{y}_i)^2}{p}$$
$$MAPE = \frac{\sum |y_i - \hat{y}_i| / y_i}{p} \times 100 \tag{2}$$

In the equations, y_i denotes the actual value, $\hat{y}_i$ denotes the assessment value, p denotes the amount of assessment samples. In Table 1, MSE in the proposed model is 18.16 and MAPE is 0.53 with equation (10) while MSE and MAPE are 76.54 and 0.79 respectively in BP neural network model, which illustrate the accuracy of the proposed model for hybrid construction costs assessment is higher than that in traditional BP neural network model. The assessment results of the proposed model can well match the actual results which demonstrate the proposed model has advantages and practical values.

The assessment errors comparison between the proposed model and BP neural network model for the hybrid construction costs are described in Fig. 1 in which the errors of the proposed model are less than those in BP neural network model and the assessment errors of the proposed model remain around 0.12 while those in BP neural network model have obvious fluctuations.

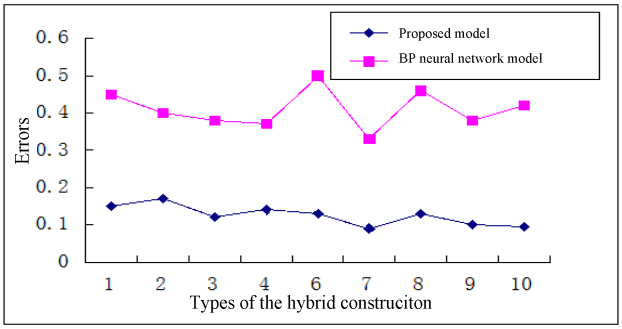

Fig. 1 The error analysis of different hybrid construction cost assessment models

4 Conclusions

This paper presents a hybrid construction optimization model based on multi-cost information reasonable constrains which can effectively increase the predication accuracy for the hybrid construction cost assessment models. The experimental results show that the proposed model can accurately evaluate the costs for different types of hybrid construction costs with higher efficiency.

Keywords: organization design; VSM; HZMB.

Abstract. Based on describing the status of the organization structure of the related projects at home and abroad, the construction scheme and the project management features of the Hong Kong-Zhuhai-Macao Bridge (HZMB) are discussed, and the main operation and maintenance business after the opening of the HZMB is analyzed. Learning from the advanced organization design model-the Viable System Model (VSM), the organization operation mode of the HZMB is built, and at last a suggested solution to the organizational structure of the HZMB is proposed.

Introduction

Following the closer economic ties among Hong Kong, Macao, and the mainland as well as the increasingly mature integration of the Pearl River Delta, the demand to construct the large cross-border infrastructure and change the investment environment is becoming urgent. Therefore, the construction of the Hong Kong-Zhuhai-Macao Bridge (HZMB) formally began on 2009.

The in-construction HZMB which consists of a series of bridges and tunnels will connect Hong Kong, Macau and Zhuhai, three major cities on the Pearl River Delta in East Asia [1]. The proposed 50 km link, with an estimated investment of 72.94 billion yuan and a designed service life of 120 years, consists three parts: Offshore Bridge-cum-Tunnel, Boundary Crossing Facilities (BCF) at Hong Kong, Zhuhai and Macao, and Link Roads in these three regions [2]. When completed, it'll become the longest six-lane immersed tube tunnel, and the longest cross-sea bridge and tunnel combined highway in the world.

The Nobel Prize winner Herbert Simon once said " that the first condition of developing effectively social resources is to establish effectively organization structure" [3]. While a study by Harvard Business School and McKinsey & Company concluded that organizational structure is one of the key points of project management. Mintzberg has written extensively and significantly on the importance of organizational structure [4]. Moreover, organizational structure and design are closely entwined [5] with many aspects of human resource management.

This paper is organized as follows: In Section 1, the related projects and the project features of HZMB are investigated and summarized. Requirement analysis is taken into account in Section 2. Section 3 proposes the organizational structure of HZMB. Section 4 summarizes the paper.

Related projects

A. The Storebælt link

As a proud monument, The Storebælt link connects the islands of Zealand and Funen and is a crucial traffic artery between East and West. The 18 km long fixed link across Storebælt between East and West Denmark comprises two bridges and a tunnel. The organization of A/S Storebælt is shown in the Fig. 1:

B. Hong Kong-Shenzhen Western Corridor (HK-SWC)

HK-SWC (also known as the Shenzhen Bay Bridge) is a 5.5-kilometre long dual 3-lane carriageway of which the Hong Kong section is 3.5-kilometre. Spanning across Deep Bay, HK-SWC links up the northern end of Deep Bay Link at Ngau Hom Shek of Hong Kong with Shekou of Shenzhen [7].

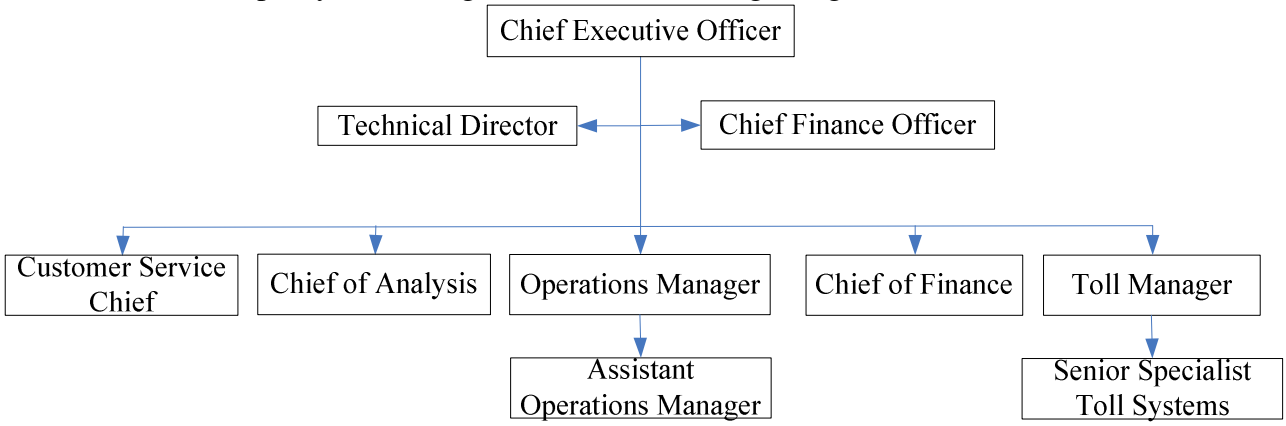

Fig. 1. Organizational Structure of the Storebælt link.

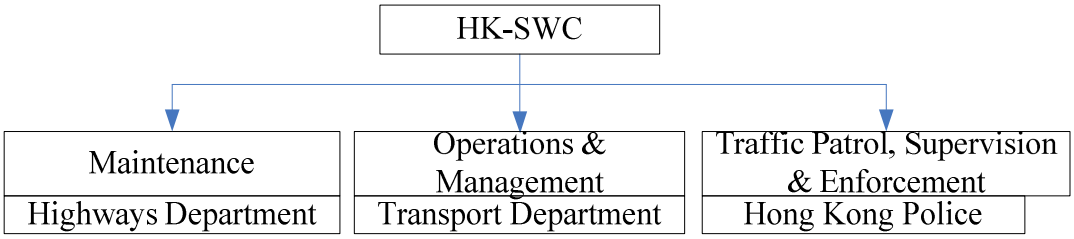

Fig. 2. Organizational Structure of HK-SWC.

REQUIREMENT ANALYSIS

The main business of the HZMB Authority is understood to fall into three categories: operation management, maintenance management and administrative management.

(1) Operation Management

The main contents of operation management include: toll, traffic management, highway law enforcement, emergency rescue, safety and environment protection, auxiliary business, etc.

(2) Maintenance Management

The main contents of maintenance management include: the main structure and infrastructure, Electro-mechanical system and equipments, roadside facilities, house-building engineering and facilities, landscape engineering, etc.

(3) Administrative Management

The main contents of administration management include: human resource, project planning, finance, logistics, party-masses, etc.

Organization Operation Mode of the HZMB based on VSM

A. Basic concepts

The Viable Systems Model, or VSM is a model of the organisational structure of any viable or autonomous system, seen in Fig.3. It has been used extensively as a conceptual tool for understanding organizations, redesigning them (where appropriate) and supporting the management of change.

Any organization needs to include two systems in place if it is to operate effectively in its environment: operation system and management system [8]. The operation system (system 1) implements all the basic work of the organization and contains several separate autonomous units, which keep contact with the external environment to adapt its change and are controlled by the management system to ensure the effective operation among these autonomous units. While the

management system, providing service for the operation system, has four systemic functions in order to make the whole organization integrally and cooperatively work. These four systemic functions are: Co-ordination (system 2), Control (system 3), Intelligence (system 4) and Policy (system 5).

All the sub-systems are interrelated and interact on each other, whose relationship can be shown from the Fig. 3.

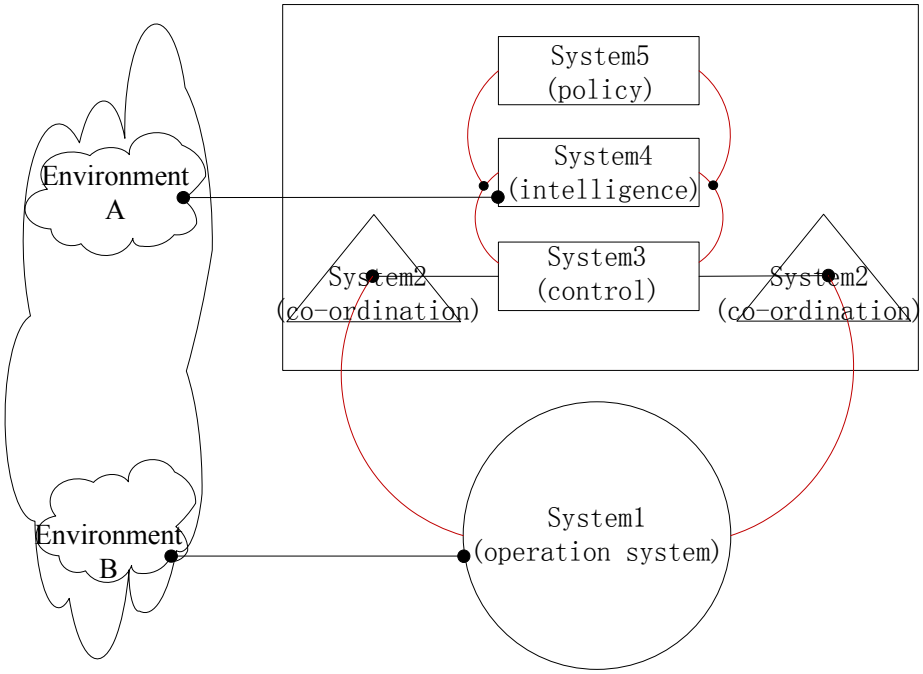

Fig.3 Viable System Model

B. Organization Operation Mode of the HZMB based on VSM

The organization operation mode of the HZMB contains five modules, which carry and build naturally upon each other, as shown in Fig. 4.

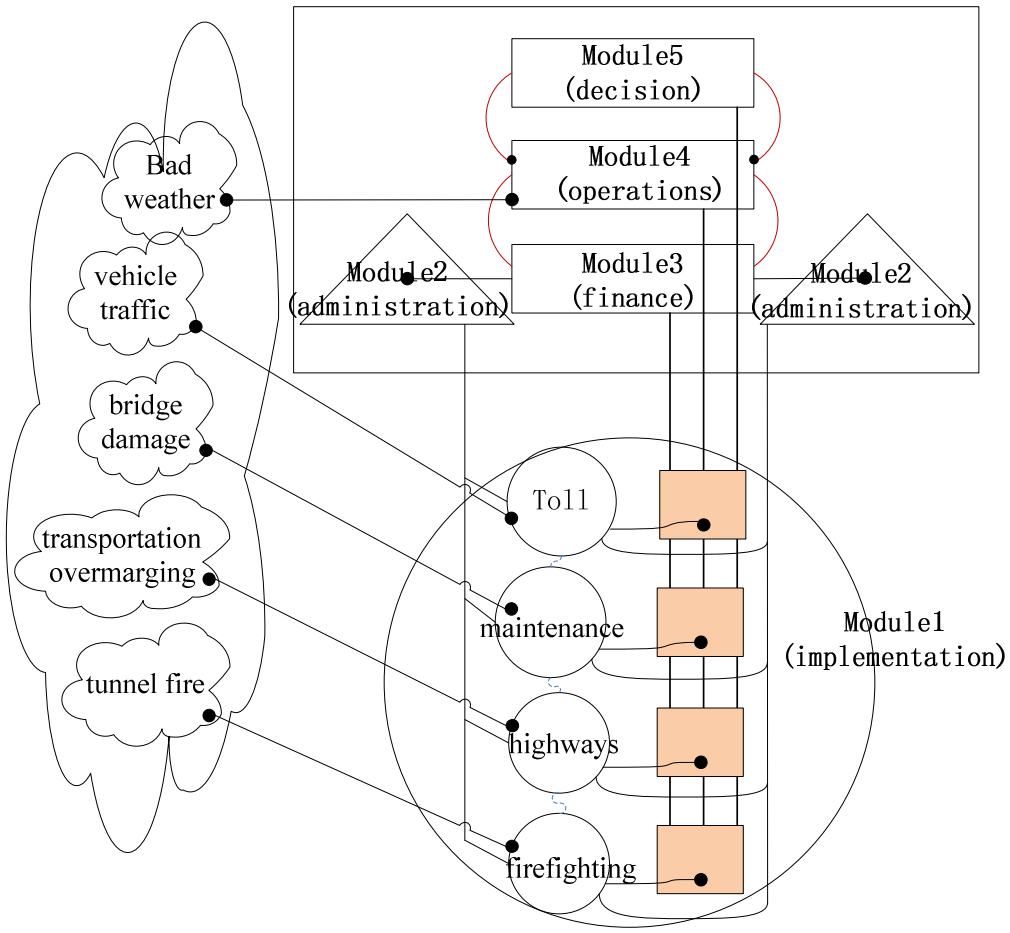

Fig.4 The organization operation mode of the HZMB

(1) module 1: implementation
This module is composed of four units: toll, maintenance, highways and firefighting.
(2) Module 2: administration
This module is responsable for the human resource, office secretary and assets management.
(3) Module 3: finance
This module not only provides finance plan and management service for the module 1, but also provides the related information about the operating situation of all the other modules.
(4) Module 4: operations
This module is in charge of acquisition of the regular operation and maintenance information of HZMB, monitoring the operating condition of the HZMB, and provide support for module 5.
(5) Module 5: decision
In this module, policy-makers make the development goals and the future of the HZMB to ensure the safe and efficient operation.

Summary

In this paper, the organizational structure design of HZMB is studied to achieve the construction and management goals. Because of the unique feature that project engages three regional governments administered under the policy of “One Country, Two Systems”, this paper could give a novel perspective for the organization design.

Keywords: Preparatory Students; Physiological; Mandarin; Speech Corpus

Abstract. In order to visualize pronunciation teaching and explore the law of articulation evolution in TCFL (Teaching Chinese as a Foreign Language), we proposed an approach to design a physiology Mandarin speech corpus for the international preparatory students in China. Preparatory students are usually beginners to learn Mandarin, so they are selected as testers to gain the most real law of Mandarin articulation evolution. The corpus was different from an ordinary speech corpus. It consisted of not only text information (such as age, gender, nationality, mother language, Mandarin learning experience, etc.) and audio information, but also the physiological data (such as speech organs' moving morphology). When the corpus was constructed, data were gathered by a supersonic collecting system because of its safety and low cost. In the initial experiment, 21 initial consonants, 36 simple or compound vowels and tones were tested. The results showed the corpus was significant in Mandarin teaching.

Introduction

The reason why human beings can speak, in physical way, is that the phoneme is pushed out by airflow, via the adjustment of tongue and the resonance of vocal tract. So the shape of vocal tract, especially movement of the tongue is significant in language teaching. As we all known, Mandarin has its own characteristic. There are 21 initial pronunciation, 36 simple or compound vowels, and four tones in Mandarin pronunciation which usually confuse foreign learners. The most special, different from other languages, is that the Mandarin speakers use the front of mouth to speak, voice is difficult to identify its hidden features through the sense of hearing only[1].Thus, research on Mandarin articulation could reveal the secret to speak Mandarin well and make great sense for Mandarin teaching. In TCFL, it's most important for foreign students to have pure pronunciation followed by fluent expression and communication. At the same time, teachers often let students imitate their intonation with the help of pronunciation sketch map in the phonetic teaching. As the phonetic is often accompanied with complex movement of speech organs and manner of articulation, the pronunciation sketch map can do a little work, the students can only rely on their feelings to adjust their articulatory state. That's why foreign students and teachers can get the meaning of each other, but it doesn't work when communicating with the ordinary Chinese people[2].It is inefficient to meet the demand of TCFL.

Design of the Physiological Mandarin Speech Corpus

Corpus in modern linguistics refers to finite collection of machine-readable texts, sampled to be maximally representative of language variety [3]. In this paper, we design and construct the Mandarin speech corpus for the international preparatory students in China based on the physiological features of pronunciation to help students learn Mandarin pronunciation accurately and successfully. By the corpus, students recognize intellectually what kind of errors they may have and researchers can get abundant and accurate data useful in TCFL research field.

The corpus consisted of not only text information (such as age, gender, nationality, mother language, Mandarin learning experience, etc.) and audio information, but also the physiological data (such as speech organs' moving morphology).

Data Gathering

1) Testers Selecting

As the first batch of preparatory education Demonstration University for foreign students studying in China under Chinese government scholarship program, there are many preparatory students every year who are usually beginners to learn Mandarin in School of International Education, Tianjin University. To gain the most real law of Mandarin articulation evolution and take advantage of the stable and abundant human resources, we choose them as testers.

Preparatory students leave away form their own countries to China at first time. Everything is brand and new for them. Good care and protection from teachers and classmates is really needed. Therefore, they need more humanistic concern than Chinese students. We need explain the meaning of experiment and how to do it so that the participants can support the experiment and does it well. The experimental equipments must be harmless and test itself mustn't hurt participants. To avoid psychological stress, participants should be in good psychological quality and adapt to the life in China. During the test, experimenters should enhance the participants' sense of responsibility to make sure the reliability of the result.

2) Instrument

According to professor Wei jianguo's research (School of Computer Science and Technology in Tianjin University), there are many methods to observe and record the motion of interior speech organs such as ultrasound equipment, EMA or MRI(Magnetic Resonance Imaging). Particularly, the ultrasound can acquire the images in the speed of 60 frames per second [4]. In this paper, we choose a ultrasound system to gather data. Hence, compared with EMA and MRI, the ultrasound equipment is cheaper, more portable, more comfortable, and high frame frequency. The ultrasound system is designed and developed by School of Computer Science and Technology in Tianjin University based on the portable TERASON T3000. Audio information is recorded via high-quality microphone and then saved as audio files. The information of speech organs' motion morphology observed by ultrasound equipment will be saved as high resolution image.

a. Function

The system is able to collect both ultrasound and audio information. The portable TERASON T3000 can display the current motion of tongue in the max speed of 85 frames per seconds (steadily，60 frames per seconds and below), and every frame of picture will be directly saved as BMP in the local disk. The default size(maximum) is 640×480(can lower). The bit depth 8 and the size of every picture is 302KB. High-quality microphone and sound recording program is used in the system to handle the audio files. The format of audio files is wav. The default parameters are shown as follows: mono, 44.1 KHz (sampling frequency), 16bit (quantization bit). The parameters can be set to meet the actual demand.

Data acquisition system using multi-threading technology makes synchronize data collection available and it records the systematic time to ensure synchronization among the data steams. While collecting the data, the system automatically generates the text files to record the basic information of each picture such as systematic time, serial number and the time of "every frame" in audio streams. With the serial number, experimenters can get the situation of image collection: they can know if there is a picture missing or time losing. When collecting the audio information, the audio files are saved in hard disks frame by frame. When each frame of audio is save successfully, the system will access the image acquisition threads to get and record the serial number of the image so that experimenters can verify the synchronization of each data stream.

b. Modules

Based on categories of data, there are two main functional modules: audio acquisition module and ultrasound data acquisition module. The audio acquisition module can be divided into different parts: real-time display of audio files, data acquisition, parameter setting, and parameter status

display, naming and saving. Ultrasound data acquisition module also can be divided into some different parts: real-time display of ultrasound data, parameter status display, parameter setting, naming, saving, and setting and display of ultrasound's parameters.

Data Processing

1) Original image

Ultrasound display the motion of tongue in the max speed of 85 per frame, and at the same time, each frame image is saved as BMP into hard disk. We should make sure that files are named well in detail. Images' default size(max) is 640×480(can lower) . The bit depth is 8 and the size of each image is 302KB.

2) Profile of tongue

Professionals analyze, compare and synthesize pictures that are taken before and after a steady speech, and finally the shape of tongue is drawn as a curve. Then the image is saved.

Via these equipments both voice features and the motion of speech organs can be analyzed. Hence, the corpus has abundant content such as text information, audio information, and speech organ's motion morphology.

Initial Applications

Technology Roadmap

The corpus can be used in TCFL, the technology roadmap is shown in Figure 1. Firstly, we collect text and audio information by the advanced instrument of observation like ultrasound equipment or high-quality microphone. Preparatory students' speech data, physiological form of speech organs and motion data can be well collected, and then be inserted to the database. Secondly, the bias error of Mandarin pronunciation is analyzed with concluding and analyzing the data we got. The pronunciation will be repeatedly examined and adjusted continually when teaching and learning.

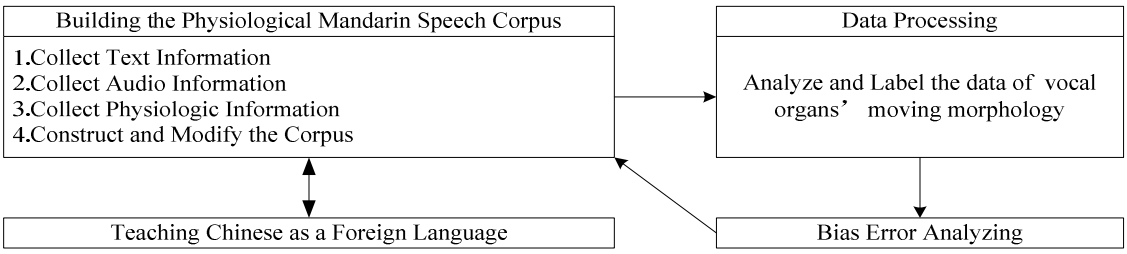

Fig.1. Technology roadmap

Experiment

At the beginning, 21 initial consonants, 36 simple or compound vowels and Mandarin tone should be tested. This time, we choose four preparatory students who start to learn Mandarin from the very beginning as testers, and then we choose three different periods in a term to do the test. The test content is the same: initial consonant, simple or compound vowel and the Mandarin tone.

Firstly, the original pictures were gathered by the ultrasound audio data collection system, as show in Figure 2.

Secondly, the professional described a curve of the tongue after analyzing, comparing and synthesizing many pictures of a stable pronunciation, as shown in Figure 3.

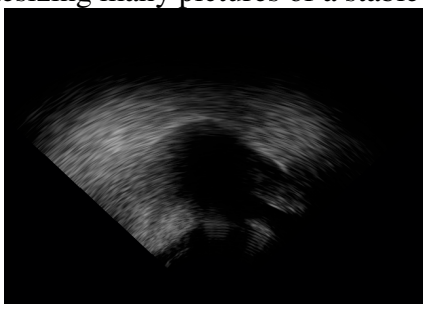

Fig.2. Original image of a certain frame by ultrasound

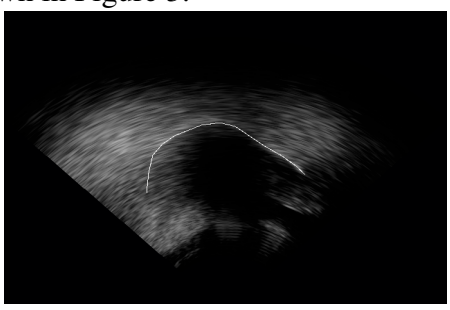

Fig.3. Final shape of the tongue

We import the corresponding audio files to the Praat, find the image that formant is steady. Ultimately, a final tongue position image was formed after comparing and compositing those two pictures, as shown in Figure 4.

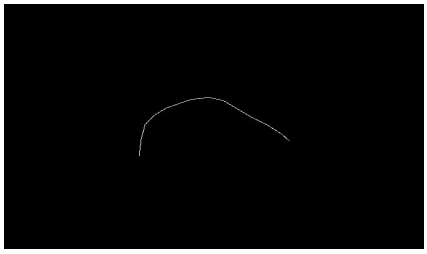

Fig.4. The final position of tongue

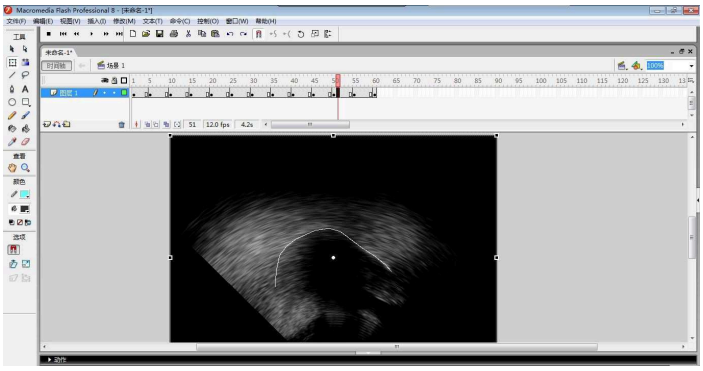

Fig.5. Animation of the tongue's movement

The system uses a high-quality microphone and recording program to acquire and process audio files in WAV format. Using the Praat software, we can observe other language features and acquire data in need. This process needs cooperate with research on experiment results and applications. To make the best of the experiment results, we will continuously analyze and mine the data deep.

The tongue is one of the most significant speech organs which can distinguish phoneme. The tongue position control is basic condition, but it's difficult to position the tongue with ears only [5].After comparing test results acquired in three times, the progress and changes become obvious. In this experiment, verifying and comparing the results in experiment with teaching rules, we can summarize all kinds of mistakes that can be made by foreign students in different phases. The images we get can show difference between right tongue position and tongue position of foreign students.

Application

1) Learning curve of phonetic learning

The acquisition of experimental data consists of horizontal and vertical features. Vertical feature is that experimental test should have phases and traceable properties. It has been widely accepted by the teachers that the foreign students who learn Mandarin as beginners have terrible bias errors in the first two weeks. Influenced by their mother tongue, students make kinds of mistakes from pronunciation to the Mandarin tone. It makes great difficult and obstacle in Mandarin learning. With in-depth study, some foreign students can comprehend the way of Mandarin pronunciation and tone so that they make a great progress, but others are not. Some students even can't have access to the way of learning Mandarin in a long time. They can't get language sense, often memorize tone and the word mechanically without understanding, or always find it's difficult to learn Mandarin and don't know what to do.

2) Finding out the systematic error pattern

With vertical comparison, we can observe the process of participants' study, the problem they are faced with and situation of promotion. The horizontal feature is capturing the prime vocal feature in different phases, especially for the wrong vocal feature and the habitual mistakes. Even the common problem encountered by the learners from different countries or different language background is analyzed so that we can develop targeted method to improve the situation. The corpus can show the characteristics of native speakers and the systematic error pattern of foreigners. Getting the error pattern of a specific learner group is of great importance in improving teaching method of Mandarin disyllables.

3) Pronunciation demonstration animation and the computer-assisted language learning (CALL)

We can develop some animations and video games to show how speech organs motion or make some models or toys to simulate the motion of speech organs. We had make a simple animation (as shown in figure 5) which can show clearly the movement of the tongue when pronounce a specific pronunciation. We can also compare this with the standard mandarin pronunciation and find the differences. So it is easily for the foreigner students to learn Mandarin by themselves through the

computer-assisted language learning (CALL).The literature on CALL mentions a number of its potential advantages: elimination of time limitations and dependence on the teacher, possibility to work at the user's own tempo and to store his/her profile in order to monitor the progress, constant access to a number of additional materials such as visualizations, recordings and animations as well as elimination of stress related to the fact that the learner is being listened to by his/her classmates, the last of which is particularly important while acquiring L2 (second language) pronunciation and prosody.[6]

Summary

The Mandarin speech teaching for foreign students has its own peculiarities, which is always a big problem for TCFL. Due to the complexity of Mandarin speech, different students from different countries are often faced with many bias errors. The corpus could be used as a basic database to visualize pronunciation teaching and explore the law of articulation evolution in TCFL. This corpus is a meaningful attempt. We expect it can provide support and inspiration to the future work.

Construction and Implementation of the Network Teaching System of Mechanical Design Basic Course based on Web

RAN MengChun [1, a], XIA Ming [2]

[1,2]Chongqing Vocational Institute of safety & technology, Chongqing 404020，China

[a] RanMengChun@yeah.net

Keywords: Machine Design; CAI; Web

Abstract. With the development of network education, the importance of the research network teaching system is more and more prominent. The network teaching system an autonomous, distributed teaching environment based on Web by using the network as the carrier of information, construct. Along with the network popularization, the network teaching based on Web will become one of the most important teaching modes of education in the future. Computer assisted instruction (CAI for short) is one of the most advanced means of modern education technology. This paper mainly discusses the application of computer network technology in auxiliary mechanical design course teaching. The advanced network technology in computer aided instruction is introduced in the auxiliary mechanical design course teaching, which is one of the most significant reform teaching systems facing in the 21st century.

Related technology review

1.1 JSP technology

The emergence of the Java language lays the foundation for Web application and provides sufficient technical support and implementation mechanism to establish a safe, reliable and compatible, open, distributed application system, it is on a par and the Web to promote each other, hand in hand. Web technology based on Java has deepened into every aspect in people's lives, areas covered including e-government, telemedicine, distance learning, etc. [1]The role of Java technology in the Web makes remote performance of the network teaching system greatly enhance. Java language is a kind of very good language; its good features are below:

(1) Platform neutrality. The most important feature of the Java language is that it can be run in any operating system. Using the Java virtual machine is to make support has nothing to do with the operating system and can run in any system.

(2) Security. Java takes three kinds of measures to ensure safety. First of all, Java itself in design is to eliminate the illegal operations. [2] Cancelled the pointer hackers are good at although lost flexibility fundamentally put an end to one of the most powerful damage safety hidden trouble. Good encapsulation of Java can in the program purposely prevent some object related to the system resource modified by other objects.

(3) Multithreading. To do multiple tasks at the same time within a process, a number of different threads can be designed to work separately. [3] Java does almost all the thread mechanism well and multi-thread mechanism has been implemented in the base class library. Better is that it has completed data synchronization process many other languages is difficult to implement or poor implementation of.

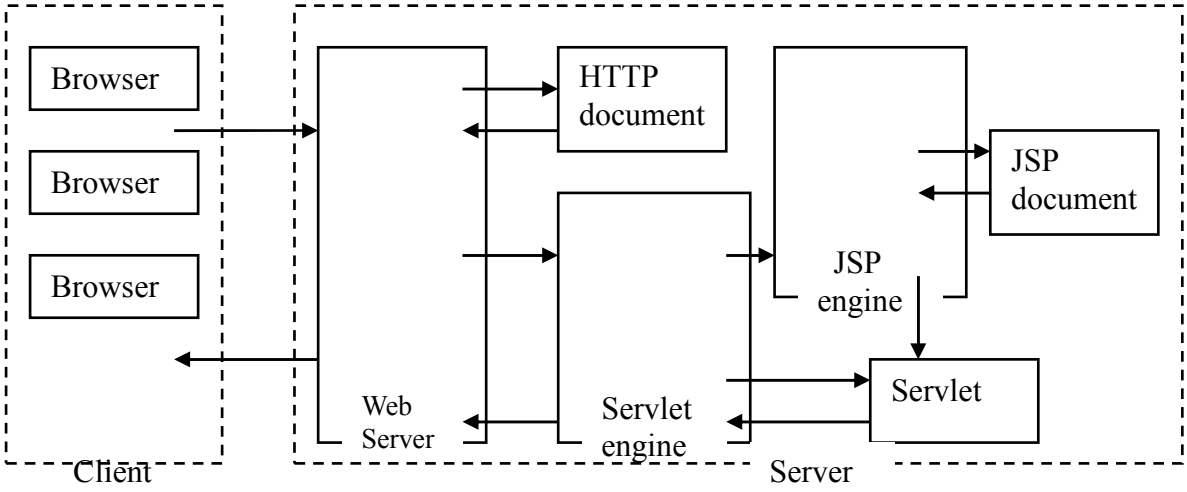

Figure1. Basic Principle of JSP

1.2 JDBC technology

Web page calls the background data in the database, so JSP and database's connection is involved, which is a very important subject. In order to manage the database, you have no choice but to use the JDBC technology.

JDBC is a kind of Java API (Application Programming Interface) that can be used to execute SQL statements. [4]It consists of a number of Java language classes and interfaces.

JDBC provide a standard application programming interface for database application developer, database front desk tools developing personnel to allow developers to write complete database application in pure Java language.

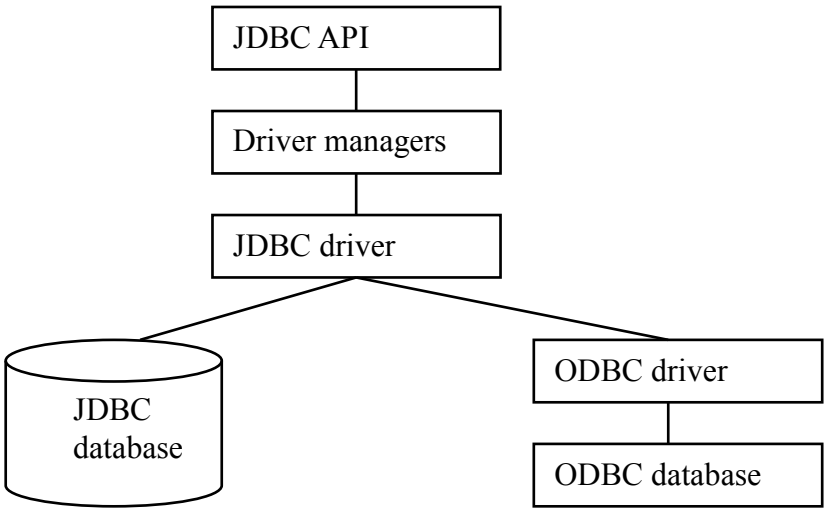

Figure2. JDBC relational chat

JDBC API (Application Programming Interface) has two different layers: the application layer is for the database Application developers; driver layer is for driver manufacturer. Figure 3 shows the application's connection to the driver.

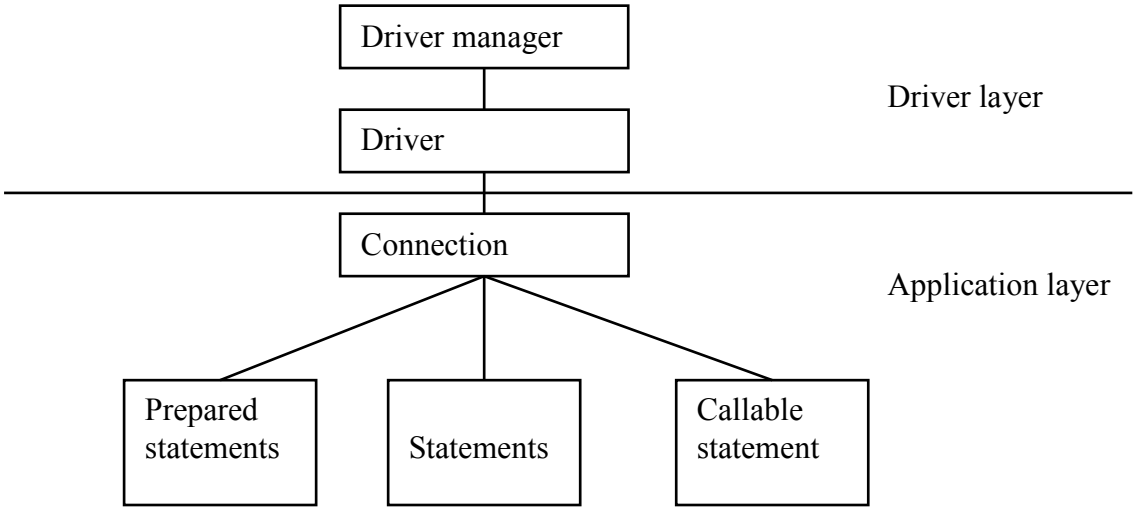

Figure3. Connection of application and driver

Adaptive testing

With the progress of society and the popularization of computer network technology, the requirements of society for workers and the technical personnel's knowledge and ability is becoming more and higher. As a measure of the ability of an important means, exam occupies further higher position in the modern life, and goes deep into the all aspects of the society. With the development of computer technology, the test methods and media is in the event of a revolutionary change, from the traditional paper and pencil test to the computer aided test, and then to the latest Web-based test.

2.1 Classical test theory

Since this century, the classical test theory has been the basis of education and psychological measurement work. The theory is also called True score theory. Its basic idea is: every individual has a certain amount of psychology that cannot be directly observed, they are called "true score" (T), we can use the “observed score"(or called "ack scores") (X) actually received, of a certain measurement error (E) as the estimated value of the true score, its mathematical model is:

Observed score = true score + error, namely X = T + E

This is a linear model; it said that the linear relationship exists between the observation points and true score. Although the classical test theory has been widely used in various types of test preparation and analysis of the test score interpretation, has a long history and has obtained many recognized achievements, it still has many insurmountable technical problems.

2.2 Item response theory

Linear model is used in classical test theory, but with the progress of mathematical research, measurer’s attention has turned to nonlinear model, and the result in the item response theory.

Item response theory model

Bright characteristic differs item response theory from the classical test theory is the ability and the difficulty on the same scale, the examinee scores (ability) related to the title number and the right number. If L is the number of subjects, r is right rate, the capacity can be represented as:

$$Ln(\frac{r}{L-r}) \quad (1)$$

Difficult degree of questions is related to the examinee number and the correct rate. If N is total number of candidates, s is for the examinee answer on the topic, the topic the difficulty can be represented as:

$$Ln(\frac{N-s}{s}) \quad (2)$$

In this way, one measuring unit unifying the ability and the difficulty came into birth, called logarithmic unit in IRT, remember answer wrong rate as O, then for probability for is right:

$$P = \frac{O}{1+O} \tag{3}$$

The item response theory of single parameter logistic model:

$$P_i(\theta) = \frac{e^{(\theta - b_1)D}}{1+e^{(\theta - b_1)D}} \tag{4}$$

Double parameters model for:

$$P_i(\theta) = \frac{e^{Da_i(\theta - b)}}{1+e^{Da(\theta - b_i)}} \tag{5}$$

Three parameters model for:

$$P_i(\theta) = c_1 + \frac{(1-c_i)e^{Da_1(\theta - b_i)}}{1+e^{Da_1(\theta - b_i)}} \tag{6}$$

Summary

Starting from the mechanical design course teaching actual requirements this paper carries out preliminary research for the mechanic design assisting auxiliary teaching system based on Web combined with the most advanced network technology. Mechanical design auxiliary teaching system software can run independently on the campus network, or wan, and students in schools and correspondence learners can learn about the course and test work by combining with their actual students. The auxiliary teaching system based on Web can greatly stimulate students' interest in learning to fully grasp the requirements of the curriculum knowledge, and at the same time also reduce the financial burden on the teachers.

Keywords: Multimedia; Image processing; Database; Information management

Abstract. The development of science and technology has entered the information age. Information rapidly grow which need be accessed by the advanced technology, the development of computer multimedia transmission provides the most intuitive the most powerful support for today's information processing. Combining health care information management and computer multimedia technology, multimedia information system design is introduced in this paper, emphatically from the technical methods to discuss the requirements of the system hardware and software environment, and put forward some design methods from the universal database to tackle multimedia database and its data model. In system design, according to the characteristics of multimedia database, much data, unstructured information, information not fixed, sensitive characteristics of voice, video, and the timeline, the corresponding solutions are put forward.

Characteristics of multimedia database

1.1 Differences between media data and relational data

Relational data is data of a certain structure and can be interpreted. Multimedia data is composed of a variety of different types of media general, known as text, graphics, images, audio, video, animation, and other different types of media. Data collection, storage, processing and transmission of these media information are through different media, and the processing of each type of media has its own theory and proprietary technology. Even if the same type of media can often have different expression.

Relational data and non-relational data are used in multimedia database to express the various types of combination of multimedia data. [1]The non-relational data is multimedia content itself, the form of binary information flow; Relational data is an explanation of all aspects of multimedia data. Because of the characteristics of multimedia data, the multimedia data is difficult to be managed by using common data management methods.

1.2 OLE (Object Linking and Embedding) control

Multimedia data use relational and non-relational data combining ways to express. As it is easy to store relational data into a relational database, the storage of multimedia data is focused on how to make the relationship between the multimedia content stored in to the database. Every kind of multimedia has its own characteristics, structure and expression; we could not provide for each multimedia a way of storage and expression. So divide the three types according to the pictures, audio and video for multimedia. So you need to set up three database tables, each table used to store each type of multimedia data.[2] As long as all three to achieve storage, all multimedia can be stored and expressed. In relational database, data cannot be divided from the structure like in a storage database, as the division of the data structure, different structure of the data stored in the database can be different in the table column, but need to have a container that can receive a lot of binary information flow. At this moment OLE controls are introduced to store multimedia data.

The realization of the function of OLE controls: OLE control properties contains being able to share data and multimedia database application software. So you just need to carry out attribute set based on OLE controls so as to realize the multimedia database and Shared data between media editing software.

Design of multimedia data model and multimedia database

Multimedia database is a comprehensive technology, combing database technology and multimedia technology; it can carry out efficient organization, storage and management for the multimedia information. But in the specific design for multimedia database, many factors need to be considered, should be able to handle a single media as well as process composite media. At the same time, also need to consider the system efficiency, practical usage, easy expand, and so on in terms of human nature.

2.1 Multimedia data model

Being the same as the traditional database, data model is the core of the multimedia database system. It make the user and the structural details of the management and storage device isolated, and abstracts the static and dynamic properties of the data, in order to provide the basis of the formal to establish the use tools of multimedia data. [3] Static attributes include multimedia data object, relationship between objects and attributes of the object, and the dynamic properties include interactions between objects, object operation and user interaction, etc.

The basic task of the multimedia data model is:

1. Support structured data (such as numerical characters) and unstructured data (such as video, sound, image, etc.) and said U attribute description.

2. Support Prescntation of multimedia modeling, namely multimedia data model can express the semantic relationship the temporal and spatial relations between media objects.

2.2 Multimedia database retrieval

The multimedia data query can be divided into different types, mainly as follows:

1. Query based on the multimedia information. Content of multimedia information has been described by media data related to media objects, so these queries are based on direct access to metadata and media object.

2. Query based one example (QBE). QBE query is by looking for an example similar to the object. User's processor must correctly specify the characteristics of the object matching examples of user's request. When conduct the similarity matching, require the user to specify or systematic analysis of the texture, color, space characteristics or provide the image of the shape of the object, and can match in whole or in part. For partial matches, the query processor must match the degree of fault tolerance.

3. Time index search. These queries are used to dealing with the media time characteristic of the object, the time features can be stored by segment tree. [4]Query processor process time indexing query by accessing with segment tree storage index information or other similar methods.

4. The spatial query. These queries can be used for processing space features associated with object, these features can be generated as the media information. The query processor can access these media data information and respond.

5. Application specific query. Application specific description can be used as metadata information storage; query processor can access this information and respond.

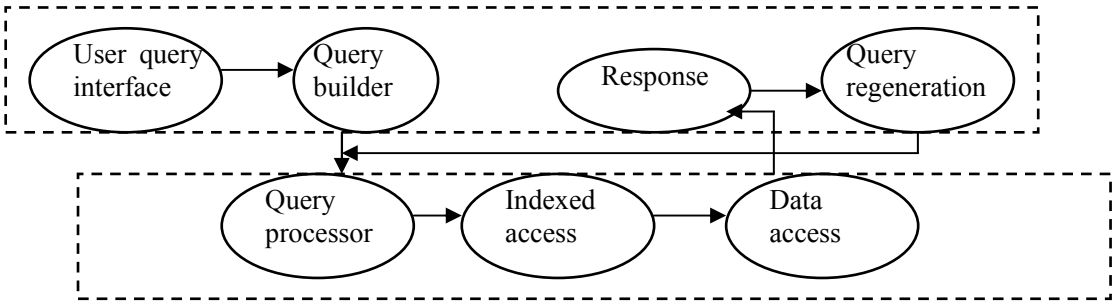

Figure1. Query management

Electronic medical record system design

3.1 Analysis of function requirement

The aim of electronic medical record system development is to record the information of the patient in an instant electronic way in order to satisfy the demands of the patient's daily diagnosis and treatment in hospital. Through the analysis it is determined that this system is mainly to achieve two roles of functional requirements, system management and medical personnel (here mainly for the doctor).

(1) System management cases

System management personnel are the runner of the system who maintains normal operation of the system. The permissions are for the entire system configuration settings and user management; such as modify the other user privileges to add or delete users, reset password, etc.

(2) Doctor cases

Doctor is the main users of electronic medical record system. The doctor may login to write case, refer to and modify the medical records, print it, add the doctor's advice, management advice, and actual operation such as printing orders.

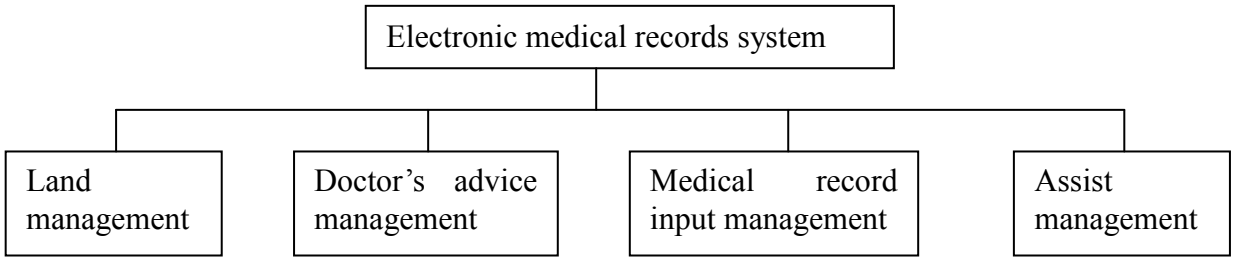

Figure2. Electronic medical record system function structure

3.2 Basic flow

The usage of basic process of electronic medical record system to is as shown in the figure below, after landing system the doctor, obtain the patient list through the HIS system, and offer the doctor's advice timely and medical records in a quick manner. As shown in figure3.

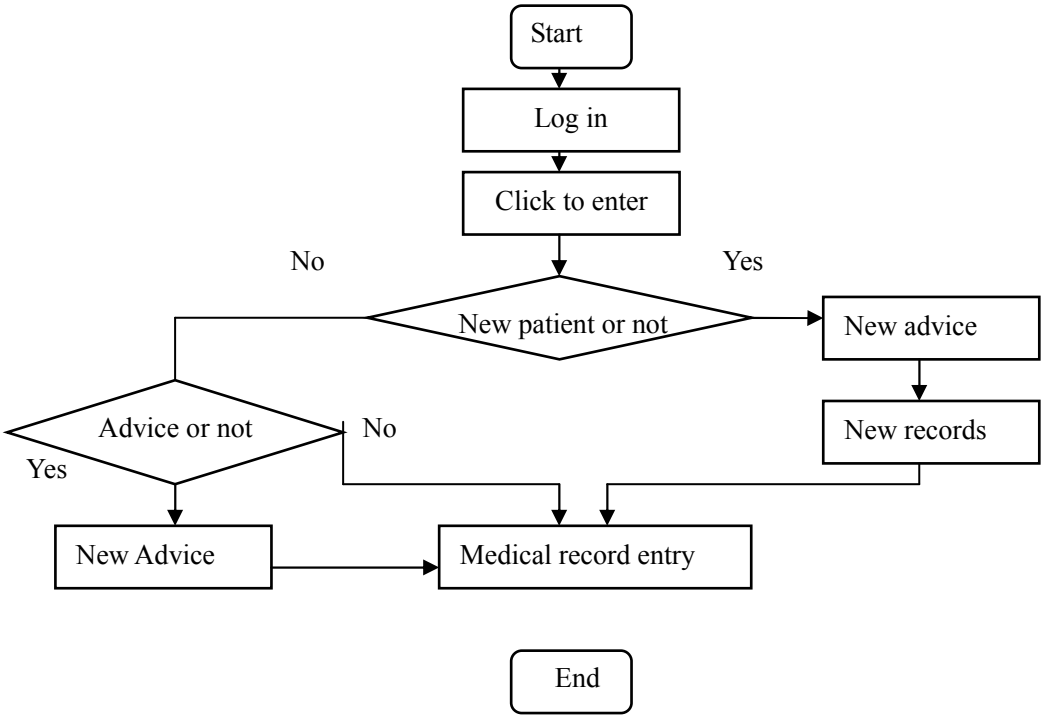

Figure 3 Basic flows of electronic medical records

Summary

Digital regional health is the inevitable trend of China's economic and social development and it is also a specific instance of the new medical health system reform. Construction of regional health information platform is an important means of promoting national health care reform, as well as to regulate information construction of medical and health industry, promote the socialization of the electronic medical records and personal health records so as to form a unified platform for the health service and health information publishing platform and health macro management support platform. Regional health information platform construction is complicated system engineering, which need the top-level design, distributed implementation. The hospital information construction is an important part of regional health information platform construction, and clinical information system construction is the main task of the hospital information construction at the present stage.

Keywords: network environment, university students, information literacy, training measures

Abstract. information literacy is not only the basic quality of college students in information age, but also a extremely important part of college students' comprehensive quality. With rapid development of computer technology, communication technology, network technology and other modern information technology, the way of acquiring information has occurred fundamental reform, so in order to survive, college students must have basic knowledge of information technology, certain information literacy and innovative thinking ability. The paper presents the current situation of college students' information literacy education, and puts forward relevant countermeasures.

Introduction

The concept of information literacy evolutes from the concept of library literacy and was first proposed by American information industry association chainman Paul Zerkowski in 1974. He defines information literacy as techniques and skills using information tools. With deepening study, the understanding of information literacy is deepening. In 1998, American library association and education communication and technology association jointly designated 9 information literary standards that students should study. In 2001, American higher education association passed through the "information literacy competency standards for higher education", which includes 5 standards, divided into 22 executive standards and several sub items. Information literacy training is extremely important and is the basic quality of lifelong learning for students.

Present situation of college students' information literacy training

University students' information literacy influences the success of quality education, and is of great help to upgrade college students' comprehensive ability. However, there are many problems existing in information literacy education.

School infrastructure investment is not enough. University information construction has direct impact on students' information literacy training. Good information construction is conductive for students to touch a variety of media and information tools, and to enhance the ability of using the information tool and information consciousness. However, informatization construction in universities can not keep up with the development of school, which leads to that the opportunity of contacting with media and various information tools reduce and hinders the development of students' information literacy.

Teachers' information literacy needs to be improved. College teachers lack the consciousness of information technology application in teaching, and most are limited to use multimedia to display teaching content while ignoring that effective use of information technology is important to college students' physical and mental development. In addition, in the process of evaluating teachers, universities always pay more attention to scientific research achievement, which cause teachers only to emphasize scientific research achievement and ignore teaching. Most teachers give students echo what the books say, and ignore the mining of information resources, thus affecting the development of students' comprehensive ability.

College students lack the sense of information. Most students in primary and secondary schools accept the "spoon feeding" education. They used to passively receive information rather that take the initiative to obtain information, which makes college students' main information resources from traditional classroom teaching and textbook. And because lacking teachers' effective guidance, quite a few students cannot acquire information through computer network, TV, or media, and underestimate the importance of information literacy.

Information ability is not enough. College computer teaching evaluation emphasizes on basic knowledge while neglecting students' comprehensive ability. Therefore, a considerable number of college students' computer operation level is limited to webpage browsing, simple software using, information collection, which causes the waste of information resources and the lack of comprehensive application ability.

Information ethics is incomplete. With the development of science and technology, information becomes easier to acquire. Quite a part of college students insist on "ism" attitude. In recent years, students' plagiarism events and network events occur more, which shows college students' information morality and concept exists problems.

Computer application courses lack effective integration with document retrieval course. The course of computer application has become the basic course of college students. Its key is to make students to have certain computer operating ability. Document retrieval and application course emphasizes that how to let students acquire and use information by using information tool effectively. In actual teaching process, the two are often disconnected and have no relation with each other. Technical course don't attach importance to the application, and the ability course learning neglect the importance of operation skills. So it causes students' technology and ability separated.

The main factors influencing the information literacy of university students

College students' information technology ability is not enough. College students possess the ability of information retrieval, but they are poor in how to use the internet to obtain information, analyze and evaluate information, integrate information into the existing knowledge structure. The initiative, consciousness and self-discipline of using information technology of college students cannot meet the need of lifelong learning and autonomous learning.

The effect of information environment. First of all, resources about special education seem to be all in a mess, and teachers and students hardly can find resources suitable to teaching and learning. Some network educational resources are not suitable to school students, which make many students embody low learning efficiency and get poor learning effect. Secondly, the network disorder also become one of the important factors hindering the people's behavior, which mainly display as slow speed, network virus, hacker intrusion, and so on. Thirdly, variety of network information is easy to disturb students' study, especially the students with poor self-control.

Information literacy education is lagging. The rapid development of information technology makes the hardware and software update quickly. However, about how to use information technology and the effect research of information technology on education, education theory and school is obviously insufficient in theory and practice. Education itself has a lot of inert, so it is not accomplished at one stroke to prompt educators and society to change education concept, let teachers use new technology correctly and adapt to new teaching method and mode in new technology environment. At the same time, software and hardware configuration was not enough to support the new teaching and learning mode. Although the network infrastructure and bandwidth has been greatly improved, from the view of computer terminal configuration and quantity, there is big distance to let all the students and teachers comprehensively use cyber source. Software and hardware configuration can not fully meet the need of the reform of education and teaching in information technology environment.

Tactics of strengthening the information literacy of university students

Increase propaganda of information quality to train students' information consciousness, and create social environment of cultivating information literacy. College students are in such a complex social environment, in which the flow of information is throughout the network. University students' information literacy training cannot separate with the effect of society. The popularization of social information culture directly relate to the training of university students' information literacy. We should strengthen the propaganda and improve the status of information literacy. Then on the basis of enhancing understanding, put the information literacy education and training on an important position.

Further improve the public network hardware facilities. The internet is the platform for students to acquire network information. The information technology, cored as the computer and network, play positive role in promoting students' subjective cognition and information emotion. The popularity of network culture, information technology also plays an important role in training college students' information literacy. If there is no the support of information technology, it is difficult to imagine the students how to get good information literacy. In order to improve college students' information literacy, the public network hardware facilities should be established to let students smoothly in the process. Powerful hardware facilities is helpful to provide information technology basis for cultivating students' information literacy, improve students' information utilization rate, and cultivate students' enthusiasm of information acquisition.

Improve college teachers' information literacy consciousness and level. To a certain extent, the focus of a new round of competition in education is talents with rich science and technology competitiveness and high cultural quality. Training specialized teachers with high information literacy has become an important way of deepening curriculum reform, promoting information quality education, and improving education comprehensive competitiveness. Teachers are the organizers and implementers of teaching activities. A teacher with higher information literacy will subliminally cultivate students' information literacy while imparting professional knowledge at the same time, For example, teachers' information behavior. So improving college teachers' information literacy consciousness and level is the key to carry out the information literacy education. Organizing information technology training for special teachers according to a certain way, let teachers integrate information technology into various elements of the curriculum teaching system. Information technology should be internal part of the classroom like all the other teaching aids.

Innovate information technology and information retrieval course and integrate information technology and curriculum. The teaching of information technology and information retrieval is the main means of information literacy training in current countries and regions. Universities should systemically arrange teaching contents and complete learning materials, set up information literacy evaluation methods and standards by the way of public courses, compulsory courses, or elective course in the university curriculum system. At the same time, the information literacy education needs to penetrate into the teaching of course. Take the cultivation of information literacy into education goal and evaluation system of all the courses. Using the method of integrating information technology and curriculum, connect information technology with curriculum content in teaching process to complete the teaching task. Integrate the information technology, the channel of teaching means and cognitive tools and multi-discipline permeation, into course to improve teaching efficiency, improve teaching effect, and change the traditional teaching form.

Strengthen college students' network moral education. We should strengthen students' information ethics, especially the network moral education. At the same time, it should avoid that students give up thinking and tracing back to nature, and should keep the depth and thickness of traditional culture. In technology, intelligence and other aspects, students have more advantages in the network world than the ordinary citizen, and have greater influence on network society and culture. Cultivate students' social responsibility in information literacy is necessary to improve their sense of mission in network society or in virtual society, the healthy development of the real society and network society, lead the progress of network and society, and establish the order of network society.

Conclusion

Information literacy has become an indispensable ability in information age. Universities should pay attention to the information literacy education, and combine with the practice to carry out information literacy education through various means to enhance students' ability of adapting to society and social competence.

Keywords: Virtual Laborary; Teaching Reform; Resources Sharing

Abstract. Electrical and electronics laborary is the important institutions of basic practical teaching in medical colleges for the students majoring in electronics, which is the bridge to professional knowledge. Due to that the mode of traditional teaching has many disadvantages ,the introduction of virtual electrical and electronics laborary become one of the researchs in many colleges. Based on the teaching reform on electrical and electronics laborary in our college, this paper analyzes deficiency of current laboratory, determining design goals of virtual laboratory, describing its some technologies, and illustrates success of new laborary. After the lab was set up, the students' ability of practice have been improved by the teaching method—combination of virtual and actual train. Furthermore, it makes school resources sharing. The laborary has very broad prospect of application for its benefits.

Introduction

With the change from superior education to general education in colleges, the number of graduates is increasing year by year. How to cultivate students' practical and innovative ability to meet the needs of society and companies, is an urgent problem.Therefore, reform of practice teaching become a key part of school's development.The conventional mode of electrical and electronics experiment teaching do not fully meet development level of science and technology as well as market's demand.And it has several outstanding problems as follows:

- Student's scale expands continually, building a new laboratory needs a large amount of capital investment. That involves purchase of many equipments, employing lab management and maintenance of lab.
- Experimental teaching is restricted by time and place, then usage of laboratory is low.
- The traditional experiments are always simplex confimative, and they are boring. Then it do not stimulate students' learning interest and enthusiasm.
- Because of long-term heavy management and teaching, laboratory teachers gradually are out of the vanguard of modern techniques,and degradate ability of scientific research .Then they can not provide better service to college and students[1,2,3].

In view of above situation, our college begin to try a virtual network platform in the electrical and electronics laborary, which enriched contents and forms of experimental teaching to help students better understand and grasp knowledge.

Design Goals of Virtual Laboratory

For establishing the virtual electrical and electronics laboratory, our college collected suggestions and opinions from teachers and students after a long- term investigation. Finally, we determined the design goals, combining with the actual situation.The design goals are as follows:

- The student can open the webpage of virtual electrical and electronics laboratory through internet, enter the name and password of a user into individual account, then make an appointment for the experiments.

- The relevant experiment handout can be downloaded. They should preview the contents before experiment. After mastering the knowledge, students can start the experiment in virtual platform. During that time, if encountering problems which can not be solved by themselves,they can watch online teaching video for inspire or discuss with students and teachers in online communication platform.
- After completing the experiments, they should record and analysis the data, updown the experiment reports.
- For students' different levels of learning and understanding, our college use multi-level method in experiment teaching .Each project is defined as 1 point, 3 points, 5 points according to different difficulty. The students can choose validation or innovation project. Before finishing all experiments on internet,there are 10 credits left to be gained.
- Meanwhile, the students must also participate in the actual experiment in order to acquire perceptual knowledge of components and instrumentation, and learn practical and trouble shooting skills.
- The laboratory can provide some off-line simulation software and relevant tutorial downloading, such as Matlab and Multisim for their self-study.
- At the beginning of the term, the teacher can visit the virtual laboratory as a local administrator, update the experiments, import lists of students in table form and set passwords.
- During the time when students are doing experiments, the teachers answer questions online patiently and provide services. After students complete the experiments, the teachers review experiment reports and provide achievements.
- According to the professional needs of students, experimental projects can be modified and developed.

Technology Related to Virtual Laboratory

A. Architecture of virtual experiment platform

Two kinds of system structure used in the current virtual laboratory are compared, the structure of C/S (client/server) and structure of B/S (browser/server) respectively. Compared with C/S structure, B/S structure is an improved structure composed of three layers. Furthermore, it has such features as standard, low cost of creating and maintaining, providing user-friendly and flexible systems, low requirement on client, mutually independent module and high safety performance. According to the analysis, this system uses B/S structure. It is the architecture of virtual platform shown in Figure1.The whole is divided into three layers: presentation layer, function layer and data layer[4].

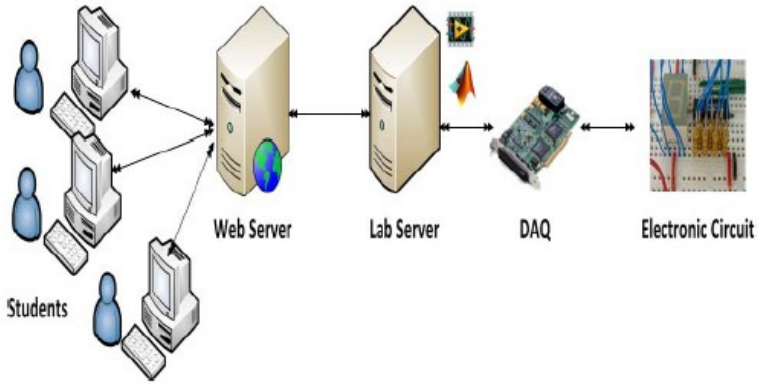

Fig.1 Structure of virtual electrical and electronics laborary

B. Development of virtual experimental environment

The virtual experiment environment is developed by Labview. Laboratory Virtual Instrument Engineering Workbenck is Labview for short. It is innovative software product developed by

American National Instruments Corporation, similar to C and BASIC development environment. The significant difference between Labview and other computer language is: Other computer languages are the code generated by text-based languages ,but Labview is the program that is writed by graphical editing language G. Its program is in form of block diagram ,and the panel and function of it is very similar with the actual instrument. It has all functions, such as the hardware that meet GPIB, VXI, RS-232 and RS-485 protocols, and the communication of data acquisition card.The standard library functions is installed internally,such as TCP/IP, ActiveX. So it is currently the most widely used, fastest and most powerful virtual instrument software. Labview development environment integrates all the tools , by which scientists and engineers can quickly build all kinds of application to solve problem and improve productivity and innovation[5,6].

C. Data acquisition system

The data acquisition system consists of sensor, transducer , singnal adjustment circuit, data acquisition card driver, hardware configuration management software, application software and computer. Its main working process is:

The physical signals is converted into electrical signals through sensor. Electrical signals becomes the data that acquisition card can store by amplification, isolation, filtering, gain, linearity etc. Then the data is processed and analysised by computer[7,8].

Success of new laborary

Since the establishment of virtual electrical and electronics laboratory in our college, it has been used for some time and get affection from students and teachers. It achieved remarkable success, and the web page of lab is as shown Fig2.Summarized as follows:

- The mulitifunctional and opening laboratory is really achieved, changing traditional experiment mode and making experiment service anytime. A new experiment environment is advocated.
- Online multimedia teaching video have rich pictures,texts and sounds, which not only provide more forms of learning ,but also effectively help students to memorize , understand and think.
- By the new experiment teaching means, the students have a solid foundation for professional knowledge and participating in Design Competition of Electronics.
- The students' enthusiasm for experiments of circuit, digital circuit and analog circuit, is increased. It demonstrates their subject status. Then many students also form interest groups, their work is as shown Fig3.
- The lab teachers decrease some work of experiment preparations and guiding experiments,and have more time to devote themselve to new experiment items. Then they can improve the scientific research and teaching ability.
- The cost of experiment teaching is lower. The problem of lack of laboratory space is solved. Usage of commodities and damage of instruments are inevitable in actual experiments, which can be replaced by the virtual experiment platform, so the money is saved effectively.
- It is safe. Failure to follow experimental instructions could result in electrical shock causing death or injury ,due to that 220V or 380V AC voltage source is used in some experiments . Nevertheless, the virtual experiment platform can avoid such problems.

Conclusion

Virtual electrical and electronics laboratory can not only solve the problem of shortage of teaching resources, but also help students give an active role in study. And the teachers' professional skills increase by it. This laboratory has a lot of advantages and is worth of generalizing. But it is still in its infancy because of some shortcomings , such as higher construction costs, not sharing resources between universities and so on. With the development of network and virtual technology, the virtual laboratory platform will be more perfect and innovative continuously and help universities foster high level talented students .

Keywords: virtual logistics enterprise, performance management, Cloud Computing

Abstract. Virtual Logistics Enterprise is a joint collaboration between multiple companies to adapt to changing market demands. These member companies have complementary resources and technologies. Cloud computing can provide dynamic resource for each member of virtual logistics enterprises mainly based on Internet-related services. Virtual Logistics Enterprise performance management can efficient and timely acquire the implementation of various companies performance objectives relying on cloud computing platform. Through cloud computing, corporate members can obtain real-time information on the implementation of the overall performance objectives virtual logistics enterprise. Virtual Logistics Enterprise Performance Management can also help member companies to improve their internal performance management. Cloud computing is efficient contact these dynamic virtual logistics enterprise members together. Virtual Logistics Enterprise member companies will be integrated in accordance with pre-set performance management objectives with the cloud computing.

Introduction

Virtual Logistics Enterprises can realize the logistics operation and management of the whole organization relying on modern computer network technology. The participating companies can work together to achieve inter-enterprise logistics resource sharing and optimal allocation. Virtual Logistics Enterprise's strategic goal is to achieve resource sharing, risk sharing, complementary advantages and other characteristics. Under the conditions of maintaining its independence, each member enterprises established more stable partnerships with other member companies.

The member companies of virtual logistics enterprise are many independent individual in nature. Virtual Logistics Enterprise performance management can effectively integrate and regulate each member enterprise resource advantages. Simultaneously each member companies will adjust their internal performance management process around the target virtual logistics enterprise performance management.

Cloud computing is a computing model that provides virtualized resources dynamically scalable by way of Internet services. The cloud computing model provides users multiple types of resources with virtualization technology. Cloud computing will promote the member companies of the virtual logistics enterprise to remain concerned about the overall performance management and actively play its positive role

Virtual Logistics Enterprises

With the trend of economic globalization, the logistics process gradually formed a trend of internationalization. Large logistics systems with international and long-range characteristics have been impossible to build by an established business. Large modern logistics system is a virtual logistics enterprise that relies on information technology and network technology support.

The virtual logistics enterprise is not an independent enterprise in fact. But the virtual logistics enterprise can put the whole system works very effective like a very large scale of independent

business. In the case of the rapid development of the information technology and the rapid development of the logistics concepts, the service process of modern logistics industry will become a new service area which involved many links, a wide range and dispersion of businesses. The object and scope of services provided by the real logistics enterprises have significant limitations. A separate logistics enterprise could not easily face large-scale international logistics needs of users across time, across regions independently. The logistics service market is facing a large number of cross-industry, cross-regional supply and demand of customers. And also the logistics service market is facing a huge number of logistics business activities occur at any time. Large number of logistics demand side need a logistics service provider that can provide comprehensive, all-weather, the whole process of logistics services.

Logistics supply and demand sides will quickly and easily reach the needs of logistics services. Modern new logistics services necessarily have electronics, networking, automation and integration features. Virtual Logistics Enterprise quickly and easily perform the flow business activities to achieve the logistics of speed, security, reliability, low cost of aim, through a virtual network of logistics organization, trade, service, management.

Virtual logistics enterprise performance management

The foundation of virtual logistics enterprise is the reality of logistics services demand side cross-regional, cross-industry. All involved in the virtual enterprise logistics service providers will focus on the formation of a logistics business with a dynamic organization. This organization will continue to change along with the reality of cross-regional, cross-industry logistics needs. Each company involved in providing services, especially logistics enterprises will closely linked. So the virtual logistics enterprise performance management must also be improved revolved around discrete organizational structure.

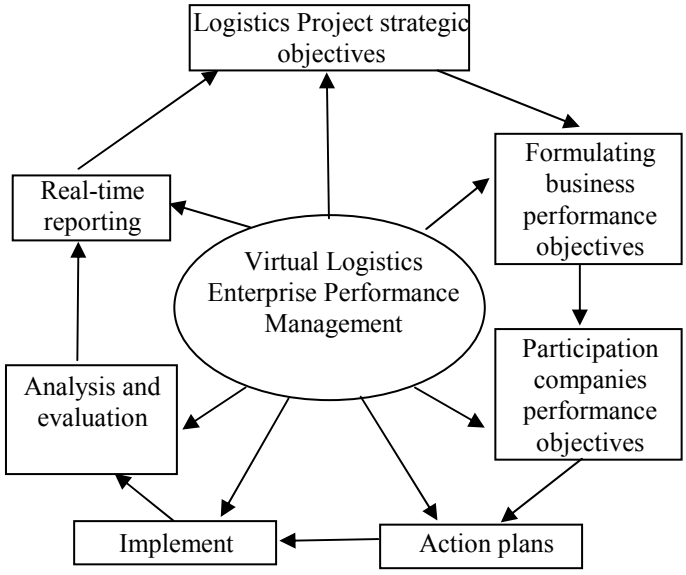

Figure 1. Virtual Logistics Enterprise Performance Management

Virtual Logistics Enterprise Performance Management is an application with interactive features across multiple industries and characteristics. The formation basis of virtual logistics enterprise has the characteristics of certain realistic needs. So the performance management for virtual logistics enterprise will also revolves around those concrete reality demand for logistics services. In this process, the actual business of the participating companies will be expanded along with the actual business of logistics. The performance management for each participating enterprise will be subsequently commenced. This set of performance management rules is the basis of performance

measurement and analysis for virtual logistics enterprises to complete the actual process of logistics services in the future.

Cloud computing and virtual logistics enterprises

Cloud computing is an Internet-based computing approach. Through cloud computing, hardware and software resources and information sharing can be provided to computers and other devices on demand. Cloud computing can provide a dynamic and scalable resources based on Internet-related services. For economic management practical activities, the spread resources are often virtualization. Virtual Logistics Enterprise member companies are involved in this dynamic organization for a logistics project. The essence closely to promote these enterprises is a virtual integration of performance management objectives.

The basis of virtual logistics enterprise is a specific inter-regional and cross-industry complex logistics project. All enterprises involved in this complex project are independent entities. Their close ties need an open platform as a basis. Currently the cloud computing can provide maximum help to them. Cloud computing provides services a unified resource space for various member companies through management, scheduling and integration of the various resources of each virtual logistics enterprises member.

The resources provided by cloud computing derived from virtual logistics enterprise virtual space. Integration of these virtual space resources is based on established performance management objectives. Each member companies are sharing their competitive advantages and the resources in the cloud space based on jointly performance management objectives identified.

Influence of cloud computing on virtual logistics enterprises performance management

In most cases, the basis for measurement and assessment of virtual logistics enterprise performance management is a pre-established performance evaluation index. The performance management and evaluation for all member alliance's dynamic are required to establish under a stable, common evaluation standards. Logistics Services objects and logistics projects environmental and other factors will generate some random variation.

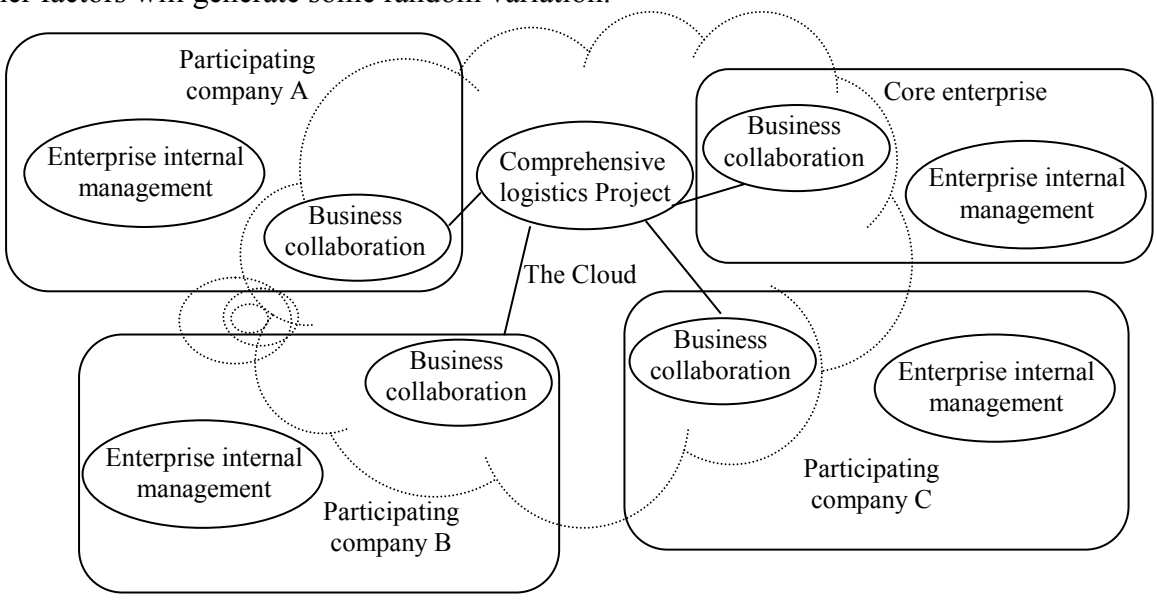

Figure 2. Virtual Logistics Enterprises Performance Management base on Cloud Computing

The virtual logistics enterprise performance management needs to establish a real-time performance evaluation and restraint mechanisms for dynamic alliance members to complete the real-time performance in order to adapt the impact of these changes. In the united underlying network

structure inherent in the companies, the cloud computing can give full play features, such as real-time, multi-faceted, multi-angle, multi-agent communication, to promote real-time virtual logistics enterprise performance management objectives.

When the performance management target system is established, virtual logistics enterprises not only pay attention to the performance of member companies, but also concern about the performance of the entire dynamic organization to adapt to the environment. Cloud computing will effectively integrate various types of information such as performance information for each member enterprise of the virtual logistics enterprise, external environmental benefits information, related industries benefit information, and benefit information related areas for the logistics projects. Virtual Logistics Enterprise performance management can be timely performance evaluation and supervision of the members enterprises based on this information. With various applications provided by cloud computing, virtual logistics enterprises can improve long-term performance management system of virtual logistics enterprise focus on specific logistics project led by the core enterprises.

Summary

Virtual Logistics Enterprise Performance Management is a comprehensive activity. Guiding role of the core business and active participation of the member companies will affect the performance management effectiveness of virtual logistics enterprise. Therefore, the effective communication platform between the participating enterprises is particularly important. With cloud computing, virtual logistics enterprise performance management can maximize the collection of each member enterprises.

Cloud computing provides possibilities of the real-time communication and sufficient information sharing for Virtual Logistics Enterprise Performance Management. Virtual Logistics Enterprise performance management is different from the traditional enterprise performance management. Virtual Logistics Enterprise Performance Management cannot periodically evaluate and assess. In most cases Virtual Logistics Enterprise Performance Management need to ensure real-time communication. The various enterprises will also actively complete the Virtual Performance Management combined with their own internal performance management by means of cloud computing information sharing.

Design and Implementation of Real Estate Sales System Based on B/S

Xiaoyan ZHU[1, a]

[1] Engineering school of economics ,Hunan communication polytechnic, Hunan Changsha,410132,China

[a]Xiaoyanzhu0427@yeah.net

Keywords: real estate sales system, B/S, design and implementation

Abstract. As the housing system reform and the rapid development of real estate sales business, people put forward higher requirements on housing sales management. In the modern information society, people who buy houses just want to get the real estate sales and selling information as soon as possible. Real estate sales agent needs to communicate with buyers quickly. Real estate sales information management system is different from general management Information System in theory and real practice, which attach more information to the timeliness of issued information.

With the development of our society and the increasing competition, real estate businessman pay more and more attention to information technology, and more real estate developers realize the importance of improving efficiency, decreasing cost and expanding business through information technology. Therefore, to develop a real estate sales system suiting the current market, and to solve problems that they meet in the housing market have practical significance.

Brief introduction of B/S.

1.1Introduction of B/S network mode

B/S mode, that is browser or server mode. It is a new network structure model developed from the traditional two-floor C/S mode, its essence is a three layers structure C/S mode. In B/S mode, clients use browser software, which asks Web server to have access to the database in the form of hypertext.[1]

Web server accepts the request, then convertes the request to SQL syntax and passes to the database server to verify its legitimacy, carry on data processing and then processed results back to the Web server. The Web server dwill receive the reverted results again, change the results to HTML form, forward to client browser and show in the form of a friendly Web page.

1.2Characteristics of B/S network mode.

(1) Economics of the development, maintenance and upgrade of the system. For large software, the cost of its development, maintenance and upgrade is very high, while the frame structure of B/S model can mostly save the cost, and at the same time, the B/S mode puts forward low request to the front desk client to avoid the tremendous blind cost on hardware upgrade.[2]

(2) It can be cross-platform operatied. The client only need a WWW browser as the applicated software in B/S mode is based on a Web browser. Some browser interface are similar which can reduce the training fee of the software.

(3) B/S mode has good openness and scalable. In B/S mode, the external users can also visit through the browser.

(4) B/S model has stronger information system integration. B/S mode integrates different kinds of services instead of scattered a single problem, which can provide higher working efficiency.

(5) B/S mode provides flexible exchange of information and the service of releasing information. B/S model can effectively solve the problem of a large number of irregular information exchange inside the company with the help of the Internet information release and transmition.

6) B/S mode provides the most realistic basis of online, network openness, unified service of heterogeneous machines, heterogeneous network, heterogeneous application service.

1.3Reason for adopting B/S network mode.

The traditional information system based on client/server mode need to install application programon the client and configure database.Every time when using it, the work is quite tedious. As

the prosses have been on the client in advance, security has also been a problem. While Web technology is based on browser/server mode, program is actually in the client, do not need to the client to install any program, so it can solve the problems of the existing client/server mod e well.[3]

The system based on Web technology is with the aid of the Internet around the world to make the job be done at local or can also be carried out in another place, which greatly expand the flexibility.

Design of the B/S real estate sales system.

2.1Aim of the real estate sales system.

System adopts B/S mode commonly used in the mainstream operation system platform, which uses ASP as the main development instrument. Backstage database adopts SQL Server 2000, HTML, ASP technology to edit web pages, and uses ASP technolog to associate SQL Server 2000 database with dynamic web pages, so the building information can be preserved and updated timely in order to realize the functions of the real estate sales system and be more dynamic.[4]

2.2Design of the real estate sales system.

System adopts dynamic development based on Web database, and associates the Web with database system closely, which is built according to the Browser /

Server structure, visiting the database through the Browser and can realize the dynamic interaction of Internet information service technology. Its function includes online data query and data processing etc. The dynamic Web development of online database is increasingly becoming the core problem in Web application. How to create building intelligent interactive Web applications, how to connect the Web server with backstage database and how to have access to the database for the users are the very hot topics in the study of the current development of Web application. To understand and master the technology as a kind of Web construction technology and technical reserves have great positive and realistic significance.[5]

From chart 1 we see that Web database system basically consists Web server, database, middleware, and network protocol software, among which the middleware si responsible for managing the communication between the Web server and database, and provides the application service program. It can directly or invorke external programs or scripts to visit the database. So it can provide dynamic HTML pages related to the database and accept the users' query, shift the results to HTML page and reture back to the browser through the Web server.

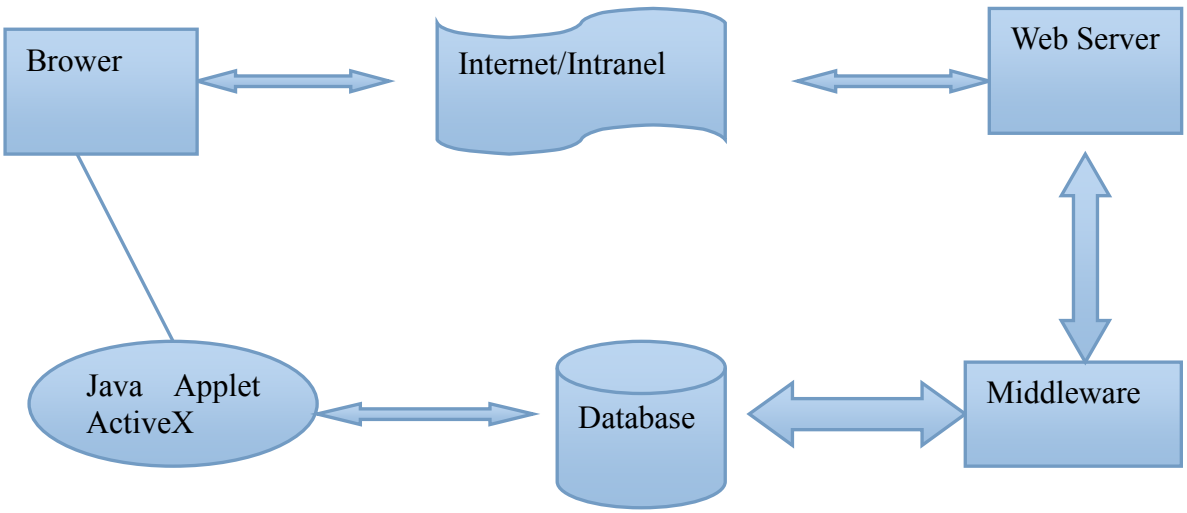

Chart 1: The Basic Structure of Web Server and database to achieve connection

2.2Process design of the system database.

The final step about data analysis is the analysis of data flow, namely to independent the flow of data within the organization abstractly, abandon the specific organization, information carrier, supplies, materials, and test data processing mode in actual business.

Chart 2 of the process shows us the fuction of the system. Information management and fow of the whole system is mainly housing dources and client information. According to the main fuction if the system, DFD at the top of the system reflects the data flow of the system on the macro aspect.

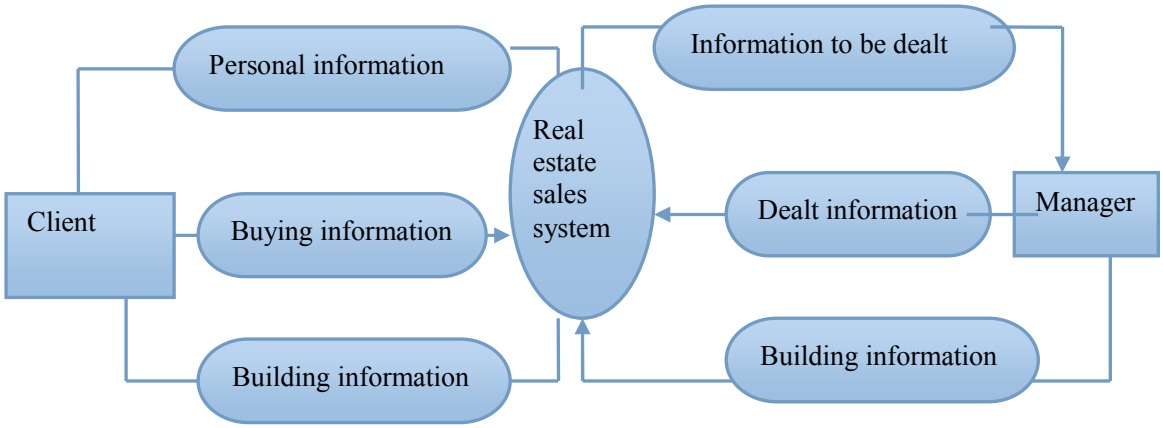

Chart 2: Chart of database processing on the top lever of the system

Implementation of the real estate sales system.

System has realized functions of the management of buildings and sales, such as users' registration, message leaving function. System also has the news reading fuction which makes clients know more about the current real estate news and common sense, which can save many time and human resources for the company.

The website of the system mainly provides the clients resources of the real estate including sales, need, renting information. The main functions of the system includes management of the real estate, management of the clients, management of the building sales, maintaining of the system, management of the system and the management of the news.

Characteristics of the system are as follows: the first one is updating the sales and renting information at any time; the second one is convenient, simple and flexible operation; the last one is friendly IOS and easy query.

Summary

At present, most of the real estate sales management system is still in the database management stage in our country, the management level is still in the level of completing some simple table printing jobs, can not adapt to the demand of the modern real estate sales. According to these situation, The system developes several main function modes from the real estate sales in the process of buying and selling.

The goal are convenient management, simple operation obvious pictures. It is of extremely important significance fo the real estate sales management and customer information management.

Keywords: computer,management system,modern enterprises.

Abstract. With the deepening reform of the management system of modern enterprises, the effective use of new technology and science has become increasingly important to every enterprise in order to make themselves in an invincible position in the competition must establish their own set of efficient operation of information management systems, the company embarked on a road of healthy development. Based on this, the paper mainly discusses the use of computer management information systems in the modern enterprises.

Introduction

Compared with the international modern enterprises business , the development of China's modern enterprises started late, so the computer management in modern enterprises also cause behind many countries and regions. Before 2000, the use of computer technology in the management of modern enterprises to manage a handful of units . Until after the country 's computer technology to develop after 2000, only a little application , but on the management level with developed countries , there are still some gaps . On current usage , although compared to the past has been a big improvement and development of the overall situation, new management techniques and measures computer just some of the bigger state-owned modern enterprises and public institutions were application , and the application and the amount of those small and medium private enterprises in less than in application mode , the application of integrated management capabilities of the computer are ignored , and only some of the individual management practices are widespread popularity and use. On the system and means in terms of the whole operation , because of the lack of uniform standards and management practices standardized , making the management of modern enterprises in the computer application is still in the lowest level stage , you can not achieve information sharing and quick delivery.

The necessity of a management information system

Development of each enterprise are never mature maturing process , the development of modern enterprises are also the same. As a result of the traditional modern enterprises using traditional management methods , making a lot of manpower and material resources and financial waste in place may not be wasted , resulting in low efficiency of traditional modern enterprises . The rapid development of modern science and technology in the modern society , a variety of high technology and equipment continue to be applied to a variety of business management process, so inevitably we need to introduce new equipment and management techniques in the management of modern enterprises to change the drawbacks of traditional modern enterprises . Then the computer management technology as an efficient and practical means of management was introduced , because the computer management techniques using a variety of complex information can be systematically analyzed and processed further in a quantitative way to express our a variety of basic information and data needed , greatly reducing the repetitive and mechanical work , the more management personnel freed from the workplace .

Development of computer information management system is an emphasis on human-machine closely systematic individualized engineering development projects. It just requires timely development and application of innovative technologies , more emphasis is kind of old management regime change. Computer information management system in modern enterprise management emphasized that the use of high technology and new equipment will change the traditional management model into computer management model , which requires the introduction of a number of specialized kinds of talent management and learning computer applications make them play their professional knowledge and skills to a variety of modern enterprise management work place .

Key in the development of management information system

Rational development principles. Many companies in the development process management system only requires software development management personnel management information system developed in line with the corporate management system to adapt now , which makes the development of management information systems in the management and application of technology are behind the times the pace of development . So, we just want to change the information management system of the computer, but to develop a reasonable development principles , emphasizing the development of a new information management system must be in a certain extent, the current management system is a technology and innovation and on measures change, rather than the previous management system duplication and imitation. Modern enterprise managers to develop appropriate policies to manage and support the establishment of a new management structure of the system.

Decisive leadership. Implementation of the success or failure of a unit can not do without a wise decision led initiatives . But individual leaders in modern modern enterprise is also a serious lack of such careful observation and close attention , mainly in the following aspects :(1)lack of awareness of information management , there is no advance information management to predict advantages and good prospects ; (20work management information system can not belong to the effectiveness of the high-income projects, but have to invest a lot of money and human resources, leadership in the face of this problem had to take a perfunctory attitude decision-making, which makes information management work carried out extremely difficult.

The key role of talent. Competition in a variety of high-tech focus to the last performance in the competition above all talent , so leading modern enterprises should pay attention to the training of professionals and computer management, a variety of operating systems and management practices of their skilled operation units , continuously updated techniques and methods for the management and planning advice unit .

Development and application of three management information system

Overall planning scheme. The total planning scheme is proposed in a variety of professionals in the theory and practice of research on the basis of details on the use of various management measures and technical computer management information systems on a variety of projects modern enterprise management information system planning and design of overall design.

The overall development of ideas. Modern enterprises is an organic unity of the whole , in the management of modern enterprises in horizontal linkages between the various projects is very important . To improve the overall efficiency of modern enterprises must then develop ideas for the future and direction of enterprises particularly clear understanding. During the construction of modern enterprise information management system, must develop a standardized overall development of ideas, projects and projects will be carried out every reasonable arrangement and layout , starting from the establishment of a database information system must be on all the items from which organic unity link chain under the management of the modern companies do a good job .

Factors affecting the development. For modern enterprises systematic management information systems planning and design must take into account the various factors affecting their development : for example, efforts to support the leadership , resources and facilities to improve the degree of near-term business development plan objectives, each a series of old species work management system and the traditional system of established standards and so on. This must be taken into account are the impact factor , because the combined effect of these factors constitute the modern enterprises standardized operation mode.

Use of Software. Modern enterprises to establish a standardized management information system is inseparable from the software using a variety of computer systems , information management system managers need to buy their own management software, but also consider it consistent with the company's other software fitness , the best use of the principle of the trial after the first purchase , and gradually establish a standardized information system suitable for their own enterprises want to use the software . We can build a team of specialized software minorities constitute a team of management personnel in the modern enterprise information management system for software testing and adaptation of Use . So not only can ensure that when we choose to external software quality assurance and software functionality they provide is that we need these personnel , can have the leisure to develop and manage a variety of small software , these developed among the software used to create the modern enterprise information management systems go . Currently , there is a certain degree of fit between accommodate a large variety of domestic and international software development , but how to choose the right and be compatible with the modern enterprise management system software is really a huge amount of work tasks. So we have specialized personnel to conduct regular training and learning , so that they better make efforts for the application to work in the modern enterprise software.

Examples of Application

Example Overview. According to wave through soft "631X" business model , management of enterprise software applications in the course of about sixty percent probability by universal test the software , the rest of the remaining forty percent , and a quarter of I belong to personalize the needs of various business units , and three-quarters of the functions belonging to various industry needs . In view of this , a variety of technical and management personnel to develop software must select the function will be added generic products in development management process throughout the software. For example: modern enterprises using computer aided management of the financial system (referred MECMFS) custom software development , including financial indicators data acquisition system, the transformation of financial software custom development and units of special requirements. Financial Indicators data acquisition system uses an incremental replication technology, financial data for each subordinate units through the " mastery " of financial analysis required for the formation of financial indicators .

The design on MECMFS.(1) questions , with all kinds of modern enterprises expanding business scale , the current management can not meet the development needs of the situation , decided to assist the development and application MECMFS financial management system . (2)System development environment. MECMFS developed on a computer , computer configuration requires good (conventional software configuration and data management language , capacity, speed and other parameters can be determined depending on the circumstances) , and with laser printers and scanners and other advanced equipment . (3)The main task . The main task is to use computer MECMFS modern enterprise financial information data query, modify, delete , and storage ; using a computer to quickly carry out this task , and can be made personalized programs and reports, to provide each kind of information to contribute. (4)systematic design ideas. System uses computer management information system development software engineering design approach to design . In this way

technical documentation is complete, create favorable conditions for future repairs, modifications. System development documentation there : MECMFS project plan ; MECMFS test mission statement ; MECMFS user manual.

The role of functional modules. (1)leading module. Module controls the entire system , built with the right port user password with select menu prompts , the operator explains how to use the system. By function selection , adjusting the various functional sub- blocks. When the operation is completed the required operating personnel , and then return to its sub-function control module ; (2)establish accounts module. Is divided into two sub-modules , database and update modules ; (3)Input Module . According to evidence a single input data, financial data content can be changed directly , you can enter the query module for viewing when they encounter problems ; (4)query module . Tip 5 function selection module , the implementation of human-computer dialogue conducted on the contents of the database have chosen to view ; (5)modify the module . Module in accordance with the financial database lateral , vertical content changes and logical addition to measuring the physical delete function.

System effects. Changed the previous system, the smaller the screen during the setup of the system , the operability is not strong and other drawbacks and disadvantages. In the course of various modern enterprise management information systems need to operate simple , powerful operating system. Use of this system was in line with the various requirements of modern modern enterprise management information system , of course , it is not without its shortcomings when dealing with issues such as finance-related , it will deal with inadequate performance , so even further improved .

Conclusion

Use a high level of enterprise information management systems is critical in today's businesses to succeed in the fierce market competition. Therefore, we must be combined with the current situation of various innovative technologies and measures , positive computer management information systems used in modern enterprise management.

Design and Realization of Computer Teaching Room Based on VMware Visualization Technology

SHAO Hongcheng[1, a]

[1]Basic Computer Center, School of Information Engineering, Yancheng Institute of Technology, Yancheng 224003,China

[a]ShaoHongcheng08@yeah.net

Keywords: Computer teaching room, VMware, Visualization technology

Abstract. As information technology is developing at an unprecedented speed, computers are widely applied in the process of teaching in colleges. A large number of universities and colleges purchase computers for practical teaching such as experiment, course design as well as visual simulation.

Due to the diversity of software versions and their differences, all teaching softwares are repeatedly installed, updated and uninstalled with the changes of courses. In such a circumstance, staff who take charge of computer teaching rooms will take on a great amount of working pressure. How to effectively meet the practical needs of all courses, release computer teaching rooms' burdens and increase the comprehensive efficiency will be a tough problem and challenge.

1. Problems in computer teaching rooms.

In order to meet diverse needs for various courses in teaching processes, computer teaching rooms in universities and colleges have to install various systematic softwares such as Windows XP, Vista, Windows 7, Windows 8 and Linux or operational softwares including Windows Office, Photoshop, AutoCAD, Visual Basic, Java and SQL Server. All of the above softwares are required to be installed in distinct operational environments and with discrepant configurations. However, in terms of computer hardwares, purchasing time as well as hardware type must be taken into consideration.

Meanwhile, in daily management of computer teaching rooms, some problems wait to be figured out. Installation of various softwares with multi-path boot in a single computer will result in systematic conflicts and compatibility problems. In addition, the large number of softwares installed will also cause prolonged starting time, dull running and worse property. What's more, the lack of safety patches and virus softwares arouses potential risks.

Therefore, how to effectively meet the practical needs of all courses, release computer teaching rooms' burdens and increase the comprehensive efficiency will be a tough problem and challenge. All of the above problems are also incomparably difficult and each of us are faced with great challenges in the near future. Design and realization of computer teaching rooms is a long way for all of us.

2. VMware.

VMware , as a pioneer and leader of present x86 platform visualization, is one of the most developed software companies in the whole world. VMware's Ballon Driver Theory, Shadow Page Table Theory and Visual Device Driving Programs have been widely applied. Besides, it is in possession of three major visualization production line, including data center visualization products, desktop visualization products, application visualization products as well as some assistance products.

VMware ThinApp is a visualization product of application program produced by VMware whose desktop visualization products cover VMware Workstation, VMware Fusion and VMware View. Data center production line is mainly server-oriented for enterprises, producing VMware vSphere, VMware GSX Server and VMware vCloud.

VMware Server is a visualization product for free and a visualization machine counting on visualization models, which can be installed in Windows and Linux. As the visiting of physical hardwares must be finished through bottom operational systems, part property consumption will occur. However, VMware Server is a perfect choice for enterprises with small size.

VMware vSphere is a visualization software set with abundant functions, being able to provide basic frames of visualization as well as application programs and management, mainly covering ESX Server, vCenter Server, Virtual Machine File System, Symmetric Multiple Processor, Distributed Resource Schedule, VMotion, Storage VMotion, Fault Tolerance, High Availability and Consolidated Backup. The following figure1 indicates the basic frame of vSphere.

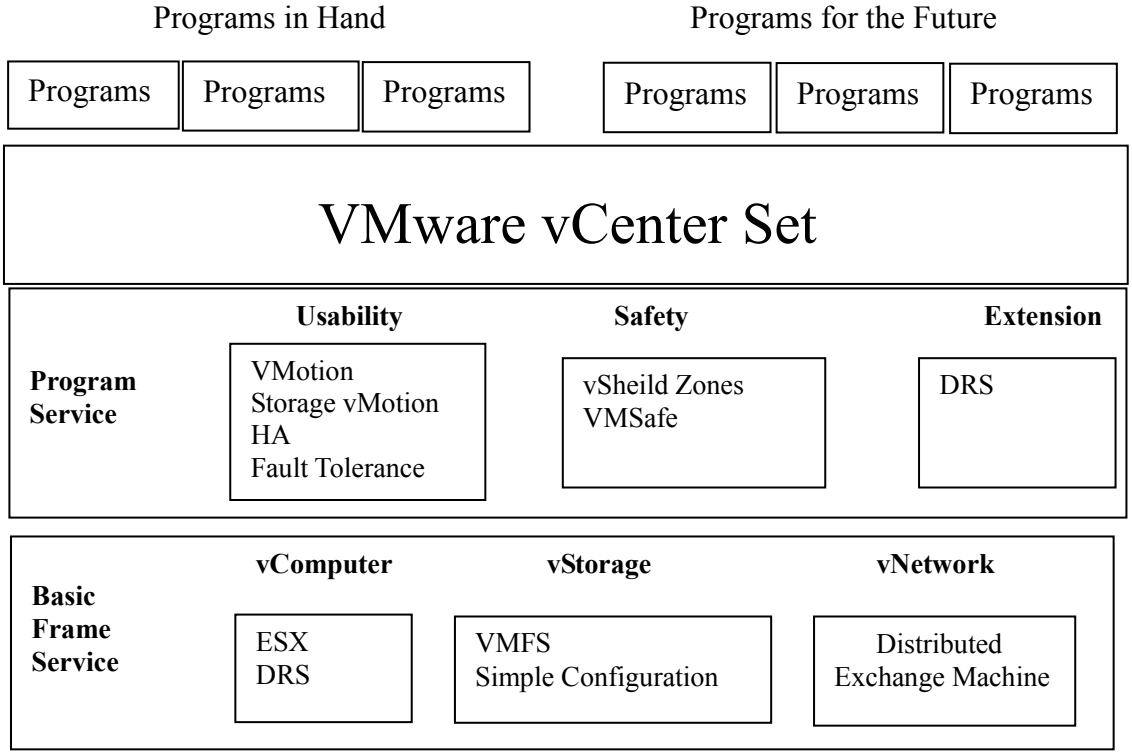

Figure 1. Basic Frame of VMware vSphere

3. Advantages of VMware visualization technology.

VMware visualization technology, as a heated topic researched by both educational and industrial circles, is in possession of some prominent advantages.

3.1 High utilization efficiency of resource.

In present enterprise data centers, for reasons of convenient management, safety and high property, the majority of x86 servers only run a single application, which results in low utilization efficiency of CPU, on average ranging from 5%~20%.

VMware visualization technology is able to integrate several servers into a single physical server to increase utilization efficiency of the physical server. In the mean time, segregation and capsulation offered by VMware visualization technology is able to make sure of safety and good property of the former server.

3.2 Low power consumption.

Power consumption in data centers mainly lies in the IT devices such as refrigeration and ventilation, but power consumption of computers only accounts for the minority. How to increase the proportion of computers' power consumption in the total consumption will be a vital problem.

Switching off the servers with low use ratio is the most visual way to save power. However, in traditional patterns, it will switch off the application when it is running in a sever if the server is switched off. In such a circumstance, VMware visualization technology is able to integrate all of the applications running in servers into few servers so that vacant physical servers can be turned off.

3.3 Rise of compatibility and acceleration of applications.

Segregation and capsulation offered by VMware visualization technology is able to segregate the platform in which applications run from the bottom servers. Thus, administrators no longer need to frequently adjust the applications according to bottom environments. A single application version keeps everything in control.

Deploying a application equals to capsulation of a operational system and a applied program's visualization machine, usually taking several minutes. Compared with traditional deploying ways, it saves manual labor, shortens deploying time and reduces deploying cost.

3.4 Reduction of cost.

Data centers are in need of constant fund to update and maintain IT infrastructures, including purchasing cost of softwares as well as operation and maintenance cost.

VMware visualization technology is able to reduce the number of physical servers so as to decrease the investment in servers and power consumption. In addition, VMware visualization technology is also able to let IT administrators get rid of a large amount of spare work which is related with physical server, operational system and compatibility problem and pay more attention to application management. In the mean time, management instruments provided by VMware companies obviously reduce administrators' working pressures, increase working efficiency and also drop IT running and maintenance cost. VMware visualization technology is definitely a good selection for reduction of cost.

4. Property data calculation in computer teaching rooms.

4.1 Use ratio of CPU.

The use ratio of CPU mentioned in this paragraph refers to average use ratio and its calculation method can be concluded as follows.

1) Extract the number of CPU and mark it as N.

2) Extract the present systematic time(the number of Ticks), subtract the systematic time kept before and finally get a systematic time gap marked as S.

3) Extract the present systematic vacant time, substract the vacant time kept before and finally get a vacant time gap marked as I.

Below formula indicates how average use ratio of CPU is calculated.

$$AverageRatio = 100 - I / S / N * 100 \quad (1)$$

4.2 Use ratio of internal memory.

Calculation of use ratio of internal memory should count on WIN32 API function and its calculation can be finished through below formula.

$$dwMemoryLoad\ (\%) = \frac{dwTotalPhys - dwAaiPhys}{dwTotalPhys} * 100 \quad (2)$$

4.3 Storage utilization.

In Windows, storage utilization refers to the utilization of all logic drivers and its calculation conforms to below formula.

$$DriverUtilization(\%) = \frac{driverTotalPhy - driverAailPhy}{driverTotalPhy} * 100 \quad (3)$$

Summary.

Application of VMware visualization technology tremendously changes traditional computer teaching room pattens, realizes central management and flexible control of teaching softwares and figures out the common problems existing in different operational system versions as well as compatibility problems in various application softwares. Besides, VMware visualization releases administrators' working volume, increases working efficiency, prolong the lifetime of hardware devices, reduces the cost invested in computer room construction, maintenance and management. Finally, comprehensive use ratio is largely boosted.

Keywords: Finnish design policy; evaluation index system; industrial design .

Abstract: Finland is the first country that formulates the design policy, and these successful experience and lessons are deserved to be focused and studied. This paper has a research on the Finnish policy index with the factor analysis approach and Delphi Method, and sorts out the opinions of policy planners, building the index system of design policy which is used to evaluate the effectiveness and result of Finnish design policy, and then studies the exterior policy environment where design innovation drives the development of country, and provides important reference for the system summary, the effectiveness, problem and tendency of the Finnish design policy.

Introduction

Nowadays, as an advanced research field of design management science, design policy has become the important part of the strategic choice and the policy setting of countries in the world in the innovation economic age. Finland is the most successful design founded nation after the World War II, as well as the first country that formulates the design policy. It can be clearly seen that Finnish government regards design as the national policy, developing design industries by investing money and making policy, which help the country strengthen national power and enhance the international competitive capability.

In China, the research and practice of how to add the value of design creation to develop the economy at the national level are still insufficient, which is obviously different from that Finnish regards the industrial policy as a part of national development strategies to make the national revitalization policy of design. The experience of making and implementing design policy is worthy learning from and taking as reference. However, how to evaluate the effectiveness of Finnish design policy effectively and objectively needs to research and build the index system of design policy, which provides important reference for the system summary, the effectiveness, problem and tendency of the Finnish design policy.

1. Finnish Design Policy and the Development of Finnish Design Industry

1.1 Definition of Design Policy

As for the definitions of the design policy, most of them focus on the three levels, namely design national policy, industrial policy and cultural policy, which can be found from the books, Internet and documents[1]. “Design policy” in this paper refers to the public policy which is implemented nationwide, and it aims to promote the development of the nation. As a part of the national policy, aside from under the unified leadership of the central government, the design policy also needs to promote close cooperation among the departments which are related with the design industry, such as the government, the marketing intermediaries, professional association, design enterprise and other departments. These relevant departments should implement the policy from the design promotion, design education, and design support dimensions, developing this comprehensive and crossing field.

1.2 Finnish Design Policy and the Development of Finnish Design Industry

Finland is located in the Arctic, a special geographical position with forested mountains and numerous lakes which has a great influence on Finnish design tradition and culture. Finns learn about

the world through the nature and integrate the plainness of the nature and the affection of the natural resources into the design culture, which forms the character that the Finnish design pays more attention on people-oriented and natural and plain environment. Therefore, it can say that “Finland is the real hometown of the modern ecological functionalism design ”.

The support of the development of design industry from the Finnish government has entered a mature period, covering all the design promotion types at every stage of the evolution of design innovation policy among EU countries, and releasing policy to promote and assure the implementation of these activities[3]. The Finnish government made the policy of “design founded nation” in 1950s, which helps Finland overtake other Nordic countries in design. From the year of 1990 to 1998, Finland government made the “outline of leading design”. In this outline, design, engineering and marketing are integrated into the system of IDBM[4]. In the late 1990s, greatly promoted by SITRA, national commission on arts and crafts and design council, the deciders of Finland education, research, industry and politics stared to prepare and make a five-year plan of the Finnish design policy, putting forward that the design should be the main factor of the competitive power and be a part of national innovation systems. In June 2000, Finnish government released the design policy of “Design 2005”, and it was formally approved by the Finland’s parliament. Design has been integrated into the national innovation system which aims to improve the competitive power of industry in this plan. And it is a sign that “design has become a part of national innovation system”, and design formally enters into the nation’s highest level, becoming the national strategy that design innovation drives the development of country.

1.3 Main Contents of the Finnish Design Policy

As the world’s first policy outline which is advocated by the government, “Design 2005!” “is not limited itself to explain the design in the cultural dimension, at the same time, it also analyzes the design from the aspects of industry and economy”, which is a major breakthrough[4]. “Design 2005”focuses on the long-lasting impact of government’s investing in design, therefore, the government’s impact can be seen in the outline everywhere which consists of 73 measures. The outline expresses that “the executive body is the Ministry of Education of Finland and Department of Trade and Industry”, and the two departments provide the main sources of capital finance to the design industry as well as call on the the international monetary funds, professional associations and educational institutions to support the design industry, besides, they also release policy to guide the development of design industry[5].

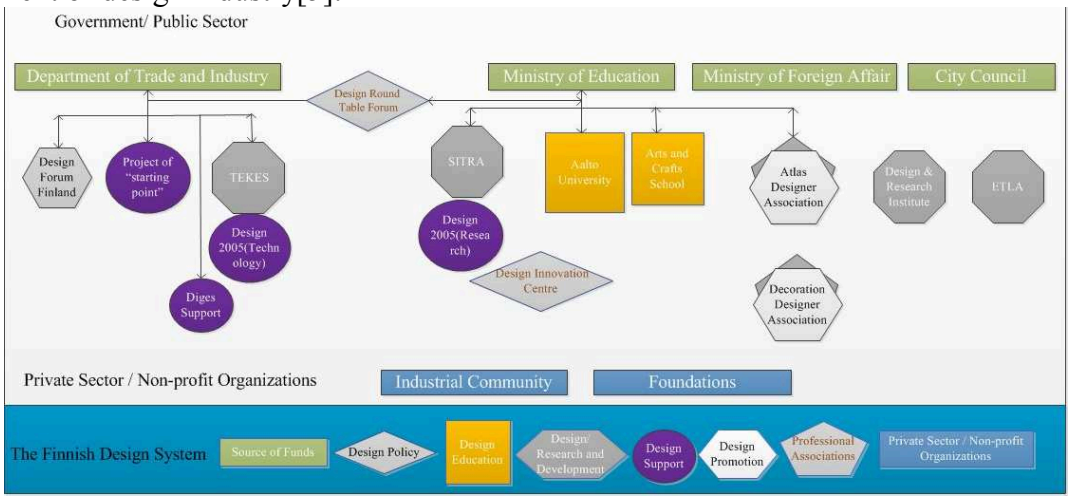

Fig. 1 Index System of Finnish Design Policy’s Assessment

Based on the actual national condition, the Finnish government enhances the direct support for research activities of design through a lot of means, for example, the Finnish government funds the technical research of design trough the Tekes and Academy of Finland. These measures include: supporting for formulating the design research standards; encouraging the enterprise to research and develop the design in the enterprise’s management stratagem; supporting the development of local

design enterprise and strengthening their operational capacity; requiring the educational and research associations to add the design speciality to their fields, and dividing up the goals of talent cultivation of various design colleges. The execution architecture of Finnish design policy is shown in figure 1.

"Design 2005" makes a tremendous splash in the world, for "the mode of combining the design with industry, national policy, culture and education" is a extraordinary accomplishment, which shows that design has been regarded as a national innovation policy, "having the right to make decision, while there was no voice for design previously "[6] .

2. Establishment of Index System of Finnish Design Policy's Assessment

The difficulty of study on Finnish design policy lies that how to evaluate the executive effectiveness of it objectively. Thus, it requires to formulate the assessment tool of "policy indicator" of the system, aiming to measure and monitor the changing industrial environment caused by executing the Finnish design policy.

2.1 Design -policy Indicators

Design-policy indicators aim to develop a set of new statistical series to evaluate the the development of design industry and its influence on social life changes. And the design-policy indicators can also observe the development trend of design industry. Therefore, the basic definition of the policy indicators should include two levels of analysis of goal and statistic. The design-policy indicators should evaluate and measure the current situation and trend of Finnish design industry and related social phenomenon after implementing the design policy through objective scientific text and data, and turn the credible economy power and social statistic into the statistic that can evaluate the development situation of Finnish design industry.

2.2 Construction Idea of Index System of Finnish Design Policy's Assessment

The goal of establishing the index system of Finnish design policy's assessment is to simplify the complicated relation among the fields which are related to performance structural systems of Finnish design policy, and to obtain more assess information by using appropriate assessment indicators. Construction approaches and procedure of index system of Finnish design policy's assessment is shown in the figure2.

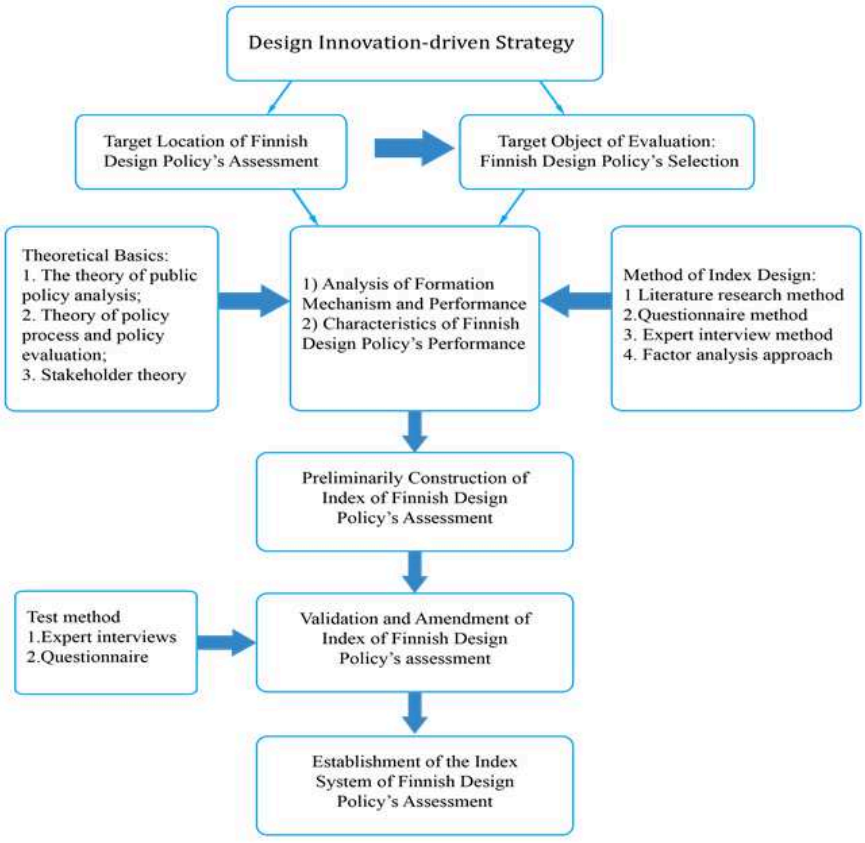

Fig2. Construction Method and Procedure of the Index System of Finnish Design Policy's Assessment

Firstly, with the guidance of Finnish design system, definite the connotation, goal and object of Finnish design policy. Secondly, based on the overseas and domestic policy assessments, the relevant theories of design industry, and other theoretical basis such as the theory of design industry development, theory of policy process and policy assessment and stakeholder theory, make a probing analysis of process of design process, the formation mechanism and performance characteristics of Finnish design policy's performance. And analyze the related fields and components of these fields which have influence on the index of design policy by applying the factor analysis approach and Delphi Method, and then design the index system. According to the index design principle and logical framework, design the hierarchical structure of index system and preliminary secondary index system and apply the expert interviews to correct. And refine the second class indicator into the third class indictor when the former is certain. At last, establish the index system of Finnish design policy's assessment. It is shown in Table 1.

Table 1 Index System of Finnish Design Policy's Assessment

First Class Indicator	Second Class Indicator	Third Class Indicator
Indicator group of industry policy	**Government funding**	1)annual growth rate of government's investment on design industry (%)
	Research personnel	2）the number of graduate of design-related colleges 3）the percentage of PhD researchers in the researchers of universities (%) 4）the percentage of researchers with master degree or higher level in enterprises 5）the number of researchers with bachelor degree or higher level per 10，000 persons
	Industry Development	6）ratio of design industry revenues to GDP 7）annual revenues of design industry 8）yearly revenues growth rate of design industry(%) 9)Quarterly fixed asset investments of design industry(billion Yuan) 10) annual growth of fixed asset investments of design industry(%)
Indicator group of cultural policy	**Culture Creative Policy**	12)ratio of the number of design entrepreneurship to the number of national total entrepreneurship (%) 13)employment rate of manpower of design industry（%） 14)ratio of manpower with bachelor degree of design-related universities in the category of cultural creativity (%) 15)the number of national work's being awarded in design in the international competition (/year) 16)the number of passing the design patent application (/year) 17)ratio of cultural consumption to household expenditure (%)
	Cultural Services	18)popularity rate of gallery and museum (/ thousand people) 19)utilization rate of gallery and museum (person-time/ thousand people) 20)times of design exhibition activities (Time/Year) 21)times of every citizen's taking part in the cultural activities of design(Time/Year)
Indicator group of Education policy	**Vocational Education**	22)ratio of population of vocational education to total population of education (%) 23)ratio of vocational education budget to total education budget(%)
	University Education	24) ratio of university education budget to total education budget(%)

		25) ratio of investment into university education equipment (%) 26) student-faculty ratios in university(%) 27) the number of college teacher's publishing papers(/year)
Indicator group of communication policy	**Information Dissemination of Design**	28) ratio of annual investment into design performance by government(%) 29) hours of government's using media to publicize the design-related issues (Hour/Month) 30) hours of per thousand citizens' attending the design-related cultural issues publicized by media per month (Hour/Month) 31) the annual average number of holding nationwide design-related seminars(/year) 32)the annual average publication number of design-related research papers (/year) 33) annual average publication number of design-related books (/year) 34) average visits of the design-related websites (Time/Day)
Indicator group of sustainable design policy	**Sustainable Design Policy**	35)ratio of achieving the goal of energy conservation design of enterprise product(%) 36)ratio of achieving the goal of resource recycling design of enterprise product(%) 37)ratio of achieving the goal of simplified packaging design of enterprise product（%）

IV Conclusion

This paper, for the progressive contents, is based on the general idea of comparative study and general domain of policy research, progressing in the way of "policy background - policy formation process - policy objective and content - policy implementation - policy evaluation". This paper analyzes the background and the evolution of Finnish design policy and clarifies the process that the Finnish design policy plays a role during the nation development; and on this basis, from the perspective of policy objective, the paper establishes the index system, and explores the index system of Finnish design policy by using the factor analysis approach and Delphi Method.

Keywords: Process; Technology; Information management; disaster prevention and reduction

Abstract. This paper analyzed research status of agricultural prevention and reduction, and summarized the three information management process stages: preparedness, response and recovery of agricultural disaster prevention and reduction. Finally, the paper analyzed information management technology model of agricultural disaster prevention and reduction.

Introduction

Crisis information management research mainly focused on the nature of crisis management and crisis to illustrate the significance of the crisis information in crisis management, thus to reveal the crisis management from information viewpoint so as to draw peoples attention on the crisis information management. As Mitroff and Pearson believes in his book Crisis Management, the gathering, analysis and dissemination of crisis information is the primary task of crisis management [1]; W.A. Wagenaar analyzed crisis information management issues and revealed the importance of information management in crisis management in Profiling Crisis Management[2]; Robert Heath proposed crisis management framework and divided information management department into information organization department, the public and media sector, consulting image management department[3];R.L.Chartrand systematically studied the application of crisis emergency communication systems and IT crisis in crisis management[4] ; Nick Collin studied the importance of crisis information management and information technology management; Sherif Kame systematically expounded the important role of decision support systems in crisis management[5]. There are also many other scholars researched on crisis management mechanisms, processes, rules and method from many aspects.

Research status of agricultural disaster prevention and reduction information management

Due to the special nature and vulnerability of agriculture, it makes agriculture often susceptible to the external environment. As the complexity of agriculture, research on agricultural public crisis early warning is difficult than other crisis warning studies. With the economic development of China, the importance of agriculture are constantly increasing and attracting more researcher research on crisis management. As BOND studied disaster losses in agriculture, and found out that if we can make the public know about early disaster information and make them take the appropriate preventive or escape behavior, it will reduce the impact of disasters effectively. Fiona Duggan and Linda Banwell built crisis information dissemination model [6]. There is studied on information processing mechanisms of early warning system for agriculture, and proposed many constructive comments [7]. However, we can find out that agricultural disaster information management researches in China is on its infancy stage through analysis of crisis information management research documents all over the world. At the same time, although China has increased investment in the construction of crisis information management [8], but the overall effect of the crisis information management is still

weaker than developed countries. In modern society, public crisis is a major social problem all countries have to face with, and is a issue related to a country's stability, security, social and economic development, and its citizen's life and property. Agriculture is one of a country's ancient core industries, therefore the study of public disaster information management in agriculture is significant, and there is a great research expansion space of the field.

Basic processes of information management of agricultural disaster prevention and reduction

Agricultural disaster prevention and reduction is a matter of the government, disaster management organizations, rescue workers, the executive branch and the general public that is high flexible collaborative decision-making process which needs continued support and rapid response capability [9]. In the course of this ongoing collaboration, the organization and dissemination of information and data play a key role. In other words, at the right time, the right place to pass the correct amount of the right information to the right people is very important. The whole disaster management process can be divided into preparation, response, recovery and reconstruction three stages. Depending on the time point of each stage, they have different tasks to be solved (as shown in Table 1). During the preparation stage, it mainly focused on monitoring: recognition and mitigation supply needs, threats and possible consequences, and further action also includes the development of new tools and technologies. Response stage directly related to the primary objective of mitigation - to save people, including victims who need psychological and physiological treatment. Therefore, action at this time including information gathering, rescue teams, health personnel and resources (such as food, medicines) transport. As the rescue operations are likely to be affected by the disaster emergency situations, new potential threats and available resources should be considered. If necessary, the decision maker should ask the country and even internationally rescue teams for help timely to provide direct security support timely. Reconstruction stage is to explore new solutions, construct and reconstruct destroyed infrastructure to build resistance capacity for any future stronger disaster.

Table 1. Tasks in various stages of disaster emergency information management

Preparation Stage	Response Stage	Reconstruction Stage
Survey	Warnings	Disaster detection
Train	Data management	Data management
Raise public awareness	Allocation of rescue tasks	Archiving, backup
Integration of information and communication technology	Rescue	Information dissemination
Cooperation of stakeholders	Cooperation of stakeholders	Cooperation of stakeholders

At the process of agricultural disaster prevention and reduction, there are interaction between people and people, people and computers. Interpersonal communication includes face to face communication, wired and wireless phones, and computers. People and computer interaction including databases, modeling and simulation technology, computer-aided, alarm and security systems, and monitoring technology, such as cameras, satellite systems, robotics and broadcast media, among them, there are three main forms of collaboration: collaboration detection tools; collaborative decision-making process; cooperation in the implementation of the resource. Collaboration often occurs among the local, regional, and national organizations. Department ready response, to be called as the reconstruction stage shown in Table 2, among them, public utility services includes local and regional level administrative departments: power, gas, sewage and water. The transport department includes local or regional administrative airways, highways, railways, waterways services. In addition, government departments, all other institutions of national and regional as well as administrative agencies all of them should incorporate into the local disaster management plan and prepare and support the work.

Table2. Agricultural Disaster prevention and reduction information management departments of various stages

Stages	Related Depatments
Preparation Stage	Designer/Planner, Mobile Communication Service Providers (Such As China Mobile, China Telecom, China Unicom,Etc.), Project Managers, Public Health Departments, Engineers, Experts, Health And Safety Executive, Security Control Center, Material Manufacturers, Media Focal Point, Propaganda Department, The Meteorological Department, Disaster Agencies, Water Sector
Response Stage	Stage Ambulances, Mobile Communication Service Providers (Such As China Mobile, China Telecom, Etc.), Casualty Centers, National Disaster Relief Headquarters, The Fire Department, The State Council, Hospitals, Security Control Centers, Medical Personnel, Media Focal Point, The Foreign Ministry, The Police Survivors Reception Center, Department Of Transportation, TV/Radio, Utility Services, People's Liberation Army, The Chinese People's Armed Police Force And The Militia
Reconstruction Stage	Stage designer/planner, project managers, engineers, experts, the State Council, materials manufacturers, the publicity department of the PLA, the Chinese People's Armed Police Force and the militia, TV/radio, public utility services sector

Information Technology model of Agricultural disaster prevention and reduction

In the agricultural disaster prevention and reduction process, information quality is the most important issue, and effective flow of information will help to promote and strengthen cooperation between the various departments rescue. It needs to identify and overcome the collaborators and technical problems due to the failure of disaster management of the process. In a disaster, there are generally four transmission channels of information flow: the internal organization of the participants (such as agriculture bureau), from people to the organization and to the people from the organization. The reliability of information gotten by decision-makers must be checked. Therefore, it is necessary to introduce data filtering function during the transmission of information flow between the various departments. Data filtering network (DFN) can minimize information overload, spreading of misinformation, releasing of incomplete information, changing information and conflicting information problems. It has three main functions: (1) collect related data and information of disaster from the public, media and specific experts; (2) organize useful data; (3) send the necessary final filtered metadata, data and information to its subordinate. Thus, the information and communication technologies play an important role in the process of agricultural disaster prevention and reduction. It facilitates the flow of information and collaboration between organizations to improve disaster planning, mitigation and management level. Information and communication technology systems should be adapted to the needs of users. However, as the number of users of the system increase, it is difficult to ensure adequate flow of information (particularly in large-scale natural disasters). Therefore, the amount of information users have to make the system fault, the risk of information loss and delay minimize.

Information and communication technology (ICT) framework used in agricultural disaster prevention and reduction is a combination of a series of orderly composition of ICT, it refers to the completion of a systematic reconstruction of ICT in certain environments interact with each other in disaster collaborative model being used by various organizations, thus forming the network to help achieve effective two-way communication in disaster management process, in order to improve the efficiency of cooperation. Figure1 is information technology model of agricultural disaster prevention and reduction. In all stages of the disaster management process, the applied information and communication technologies includes the internet, information security, computer databases, integrated data management, intelligent data management, audit tools, multi-agent systems,

multi-language support, data filtering, mobile communication technology, wired communication technologies, and wireless communication technologies. Some of these techniques can be applied to all stages of the disaster management process; others can only apply to a specific stage.

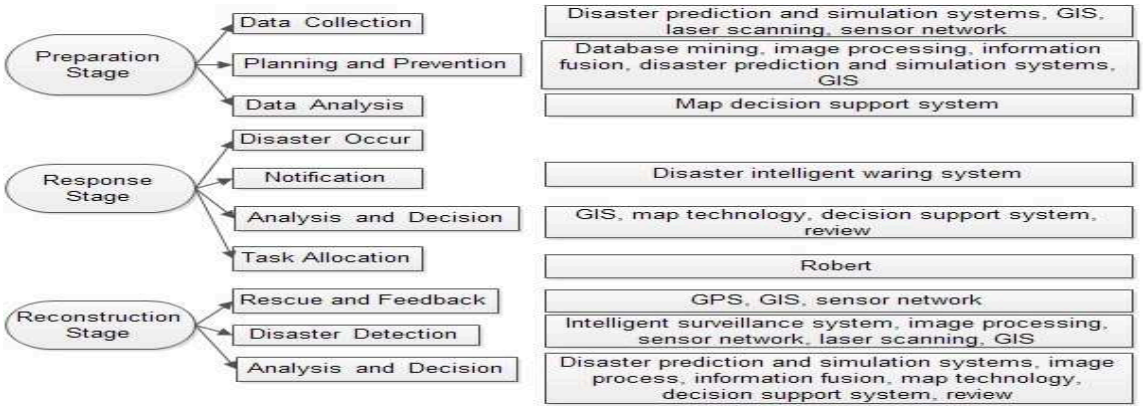

Fig.1 Information technology model of agricultural disaster prevention and reduction

Summary

The purpose of disaster prevention and reduction of agricultural information management is to facilitate the exchange of information in disaster management process, and to achieve effective cooperation among the participating departments. Information management processes of agricultural disaster prevention and reduction make agricultural disaster prevention and reduction management more effective and the work of rescue and relief timely. The information technology model of agricultural disaster prevention and reduction provide technologies basis to the construction of agricultural disaster prevention and reduction system which needed deep researches and developed system functions.

Keywords: Agricultural; Disaster prevention and reduction; framework; Information management

Abstract. The paper analyzed agricultural prevention and reduction framework research status, and summarized its design and implementation principles. Finally, the paper proposed the framework of agricultural disaster prevention and reduction information management based on the analysis above .

Introduction

With the increasing levels of agricultural information, in the form and number of agricultural disaster information is rapidly increasing. With the development of information and communication technology, it brings more opportunities and challenges to the agricultural disaster management, information sharing and information exchanging. Agricultural disaster prevention and reduction is a long-term process that need to consider the lasting mitigation of disaster impact and effective communication between all stakeholders[1]. Therefore, it's necessary to apply information and communication technology to agriculture disaster management in order to ensure successful coordination and orderly communication of decision-makers, resource providers, and victim rescue teams. From the economic point of view, to provide efficient coordination and communication is also beneficial because it time saving and supports the sharing of resources and views [2]. However, in disaster prevention and reduction of agriculture, it's not enough if there only have information and communication technology applications [3], all information and communication technologies should provide support for the implementation of specific operations, such as personnel training and infrastructure improvements.

Research status on information management framework of agricultural disaster prevention and reduction

Designing and implementation of disaster emergency information management systems provide an advanced and effective decision support software tools for mining and discovering periodic potential rules and inherent properties of disaster risks. However, the current disaster information management systems are often used disaster data warehouse product as its center and developed based on different architecture environment which meet with different needs and under different operating environment. Thus, the application architecture and extension of these systems are not unified. As environmental changes, service changes, function needs increase of disaster risk analysis [4], the original disaster information management system is difficult to adapt the changes [5]. In the past few years, with the gradual maturity of software and systems engineering, there is a growing need to view disaster information service system from structure viewpoint. As the interaction of disaster information platform and application systems becoming more complex and government agencies reduce investment on IT which bringing increasing benefits reliable pressure, all these changes need deep thinking on how can disaster information engineering and application system support disaster risk management. Meanwhile, with the rapid development of Internet technology, people are faced with massive, heterogeneous, geographically disaster information which make access and analyze of these data user difficult. To get effective disaster risk decision-making

knowledge from such a large number of geographically dispersed disaster information is an extremely difficult task which facing enormous challenges. To solve this massive problem of distributed heterogeneous data analysis, an disaster risk information resources and services integrated, open and flexible framework is needed.

The existing disaster information management systems mainly build based on available technology [6] when the event occurs which can not meet the needs of full collaborative information management. Most of them assume that the disaster management network system is built to ensure stakeholder collaboration through local city control center [7]. And disaster management network has no data filtering function which can facilitate collaboration of stakeholders and collect all of the information flow, and only has information and communication technologies which artificially manipulate data management, information flow, and as a communication tool.

Information management framework of agricultural disaster prevention and reduction is an process of integrating information and communication technology into agricultural disaster prevention and reduction processes to facilitate all participant involved in the conceptual model. It an authentication system with high degree of information security and speed, and it has data interoperability, system interoperability, automatic data conversion of two-dimensional (2D) and three-dimensional (3D)[8] , audio and text, multi- language support, automatic text summary and other features to help achieve effective communication and cooperation in disaster management process of organizations.

Information management framework of agricultural disaster prevention and reduction

The preparedness, response, recovery and reconstruction stages of agricultural disaster prevention and reduction can use various information and communication technologies to achieve specific functions so as to achieve disaster cooperative management technical support. The information management framework of agricultural disaster prevention and reduction is based on communication and collaboration difficulties and suggestion reports of relevant departments. It is designed to support and strengthen coordination and information flow in disaster management process and introduced an intelligent ICT for disaster management system involving data filtering network. Agricultural disaster prevention information management framework is shown in figure 1. In this model, Disaster Collaborative Emergency Information Management Systems (DCEIMS) have three different systems at local, regional and national level which are called local DCEIMS, regional and national DCEIMS. Compared with the existing disaster emergency information management system, the framework applies coordinate emergency information management system to the collaborative process to replace human operator of data filtering and data distribution.

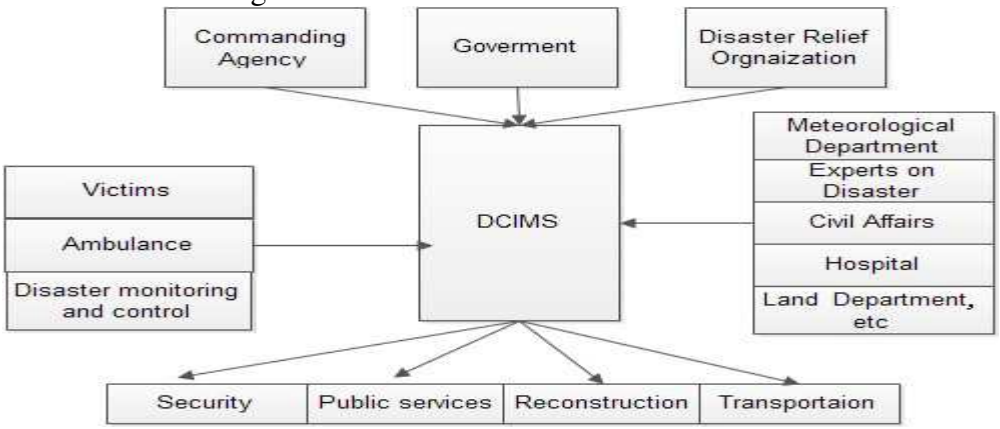

Fig.1 Information management framework of agricultural disaster prevention and reduction

Principle analysis of agricultural disaster prevention information management framework

Agricultural disaster prevention information management process has three stages: preparation stage, response stage and reconstruction stage.

At preparation stage, the local DCEIMS, as the control center, responsible for disaster management and to provide a local database, it's far from high-risk areas. Local DCEIMS system like a bridge that make cities, the public, environment building experts , regional and national DCEIMS cooperate with each other much more fast and effective. Local DCEIMS is responsible for disaster preparedness stage on the following works:

(1) Disseminate disaster information, alarm systems, preventive measures, and other information, through the media, newspapers, magazines, electronic billboards, local DCEIMS website, disaster-related sites, well-known sites, and automated messaging system to establish public awareness.

(2)Build a network database based DCEIMS training systems, and connect with all domestic local DCEIMS system to provide support of training personnel who will participate in disaster response and reconstruction. Everyone will be notified training schedule, rules changes, technological developments and changes, with permission of the information about the nature and impact of disasters through the system necessary to access, and accesses to training notes via e-mail and text messages as well as the necessary inter- discipline data. In addition, the training is to improve disaster response exercises, including simulation technology and physical exercise.

(3)Establish volunteer relief groups, and train on them by simulating specific relief activities (such as rescue and medical supplies). Analog recording will be announced and open to the public. Experts and volunteers support by synchronous and asynchronous activities based on computer, and should enable them to access certain privileges by DCEIMS training systems.

(4)Integrate available information and communication technologies to the system and to help monitor the efficiency of disaster information management. These systems inherit data filtering network (DFN), automatic data interpretation, advanced CCTV camera, intelligent early warning system. They are self-healing system, in the event of a system failure can be reconfigured, and can be specific interoperability. Each system is equipped with alternative power sources.

(5)When systems, tools or communication channels have troubles that can not be solved, the control rights should pass to the previous level.

At Response stage, disaster monitoring experts (such as meteorological bureau) provide warning information to the State Department, and analyzed information gathered from closed circuit television cameras should send to the local DCEIMS.

Local DCEIMS alerts the relevant authorities through DCEIMS systems, such as the local ambulance, police and other emergency response agencies, as well as health, transportation and utilities suppliers, etc., and activates public warning system. Citizens can know about disaster information through radio, television, Internet, mobile phone text messages, e-mails, websites, and cable broadcasting systems installed in different locations (such as the railway station). Local DCEIMS requests all parties concerned departments to take action after receiving information filtered through information filtering network. In addition, all partners are communicating with each other through DCEIMS. Mobile health services dispatched to the appropriate location, and communicate with hospitals and local DCEIMS through wireless network. Rescue teams, fire brigade and police at the disaster site with their respective departments through L-DCEIMS and portable wireless devices. Local DCEIMS using GPS and installation of closed circuit television cameras to monitor key locations affected areas in order to support rescue operations and further confirmation response action. Satellite maps of the affected areas and generates a 3D model with advanced tools to display a visual representation, and try to support the decision-making process. Predictive model is used to predict disaster affected areas and disaster relevant events occurrence probability. Web GIS is used to collect, display and share information on the disaster websites. Collecting photos of disaster areas through visual communication tools and closed circuit television cameras carried by rescuers, and these photos can be used for rescue operations in the decision-making process. Local DCEIMS have spare power supply equipment which can operate automatically after a power off. If the local DCEIMS is damaged during the response stage, the response will be automatically passed to the regional DCEIMS.

At repair and reconstruction stages: information of casualties, missing persons can be obtained from local hospitals and police stations in DCEIMS. All data confirmed in the local DCEIMS will be provide to victims' families and the media. Information from architecture and disaster experts also input to local DCEIMS database. Web GIS, aerial photographs and laser scanning technology are also used in disaster detection. Data collected by disaster specialists from disaster site will help to developed 3D simulation system to help analyze more details in disaster in to confirm the failure factors. Backup system is used to store data. Data from various data sources filtered through filter network share to all DCEIMS systems, education institutions and research centers through internet.

Summary

Agricultural Disaster prevention and reduction information management is to improving information management effectiveness to cope with agricultural disasters, and to improve cooperation effectiveness of related subjects who coped with agricultural disasters. Agricultural disaster prevention information management framework presents challenges to the construction of information and communication technology, and will promote changes and innovation to information and communication technology framework. That is to say, it is no longer the era of the simple exchange of information and people, but the form of human communication with machines, and the machine communications with equipment. However, it needs to be implemented and tested through further research on the full realization of disaster prevention and reduction of agricultural information management, especially on the development of collaborative emergency disaster information management system.

Internet Financial Innovation based on Enterprise Growth Cycle for the Small and Medium Enterprises

Yiqing Lu[a]

School of Information Management, Beijing Information Science and Technology University, Beijing, 100192, China

[a]email: luyiqing@126.com

Keywords: Internet financial; Financial innovation; Enterprise growth cycle; The small and medium enterprises

Abstract. Financing is always a big problem in the development of small and medium-sized enterprises (SME) in our country. It's necessary to develop Internet financial to support the development of real economy and improve SME's financing situation. In this paper, an analysis of the SME's financing innovation is described and then an internet financing innovation which is oriented to growth phase SME is proposed, in order to better meet SME's financing requirement in different growth phases.

Introduction

Since China implemented its reform and opening up policies, there is a rapid development in China's SMEs, which plays a more and more important role in the whole national economy and has made great contributions to China's rapid economic growth. In recent years, with increasingly fierce competition among enterprises, constraints and factors that affect the development of enterprises are gradually increasing, making enterprises facing great difficulties in further development. Among which, the financing problem of SMEs is a major obstacle to its development[1-3].

Enterprise Growth Cycle

Firms progress through four stages of a developmental life cycle, each with their own funding needs.

In the first stage, a new company begins with the seed of an idea. Its external financing needs (EFN) are high, since it needs money to develop but lacks retained earnings. These young firms are frequently financed through debt, acquiring loans from banks and acquaintances. They may also acquire seed money, a form of securities offering in which an investor (usually friends, family, or angel investors) purchases part of a business. The source of the financing may depend on the perceived riskiness and growth of the business.

After the firm is able to acquire external funding and develop its product/service, it enters the growth phase. Once a company has a successful strategy, it attempts to offer its products or services to potential customers--expanding first to other states and regions and then often internationally and globally. Successful companies can turn in increasing earnings year after year, evidenced by the increasingly steep slope in the diagram. Firms may face an increase in competitors. In the growth stage, a firm's initial EFN is high relative to its current value; it needs significant funds for growth. If it fits the specifications for venture capital (high growth potential, innovative product) a VC firm may agree to finance the firm. It may also raise capital through equity financing. As it progresses through the growth stage, earnings begin to increase less rapidly. At some point, the company may decide to go public, offering its stock to the general public on a security exchange as a means of equity financing.

Eventually, all possible customers have the product or service. They may still buy parts or replace their product with newer models, etc, but growth slows. This is the mature stage of a company's

development. If the firm has no new projects in the works, their EFN is quite low and internal funding is high. In fact, the firm may have so much in retained earnings that they cannot put all of it to productive use. They can choose to finance operations by issuing bonds and equity [4-6].

Internet Financial Innovation based on Enterprise Growth Cycle

Compared with the commercial banks in China, the Internet financial institution has more advantages to develop the financial innovation from the thinking model, cost or mechanism. The financial products shall be designed targeted to better dock the financial demands in different growth stages for the small and medium enterprises [7-8]. According to the enterprise's financing demand at different stages of the growth cycle, the financial products with different loan life and amount shall be designed; According to the enterprise's different transformation and upgrading paths, the financial innovative models of mortgage pattern innovation, financial innovation and supply chain finance shall be adopted flexibly, as shown in Figure 1.

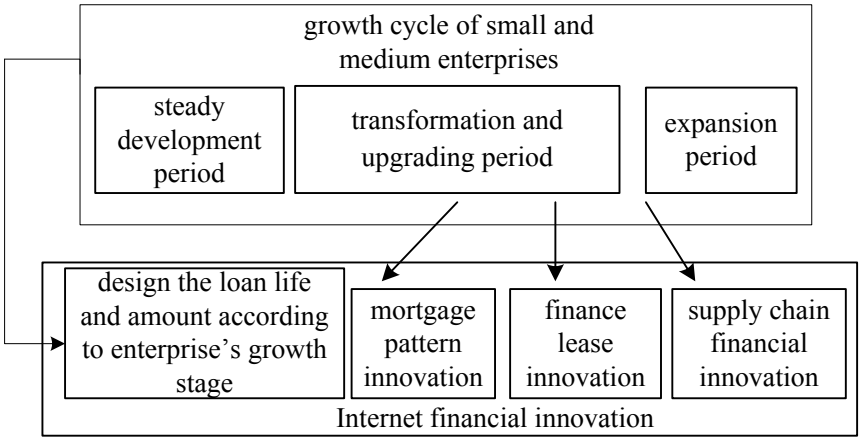

Figure1 Internet financial innovation based on enterprise growth cycle

- Design the loan life and amount according to enterprise's growth stage.

Generally, the financial aim for the small and medium enterprise is mainly to obtain the circulating fund, therefore, the small-amount and short-term loan accounts for the largest proportion in the capital structure for the small and medium enterprise with stable operation. However, in the transformation and upgrading process, the small and medium enterprise needs the fund support with a longer term and larger amount. Firstly, no matter to transform the technology or update the equipment, even including the typical cross-industry restructuring mode- exiting from the labor-intensive industry and entering into the capital-intensive industry, it needs large sums of money to support, and the usual fund supply scale with the aim to supply the liquidity in the small and medium enterprise is overstaffing. Secondly, in the product upgrading process, it is a long process from the initial increase of research and development investment to the production of new product to the channel expansion to the final sales obtaining the income, therefore, the loan with a longer term is needed to match with the process; Moreover, the industrial conversion and production base transfer and other strategies also need a stable, long-term and large-amount credit fund.

- Mortgage pattern innovation

The Internet financial institution can design the innovative mortgage pattern to solve the problems confronted in the transformation and upgrading process in the small and medium enterprise. In the process to transform from the export to the domestic sales in the foreign-based small and medium enterprise, due to different sales method, it may occur the situation of ballast product and increasing inventory, thus tightening the enterprise fund. The inventory loan can be considered, which can not only help the enterprise solve the problem of huge fund occupation pressure brought by the overstock, obtain the liquidity, but also provide the powerful fund aid for the enterprise to quickly open the domestic market. In addition to the inventory mortgage, the intangible asset mortgage can play an

important role. Most small and medium enterprises may select to improve the technical capacity and improve the product quality as the path for transformation and upgrading, while some enterprises may choose to transfer to the high-tech enterprise with small fund. The core asset grasped by these enterprises is the intellectual property, technology patent and other intangible assets. Therefore, innovating the intangible asset financing product on the technology and scientific achievements formed in the transformation and upgrading process in the small and medium enterprise can not only break the traditional fixed asset mortgage mode, open a new financing source for the enterprise, but also promote the industrialization of patented technology and promote the enterprise's rapid and healthy growth.

- Internet financing lease innovation

In the upgrading process of machinery and equipment, in order to avoid the pressure brought by the one-time amount expenses needed to buy the equipment, the Internet financial institution shall consider to adopt the financing lease form to use the fixed asset, then halve the buying expense within a longer period in the future, thus smoothing the enterprise expenditure and avoiding the large fluctuation of the enterprise's operation condition.

- Supply chain finance innovation method

If the small and medium enterprise selects to extend along the upstream and downstream supply chain, the Internet financial institution can consider to select the supply chain financing mode to provide the fund support for the process. Adopting the supply chain financing product can extend the good credit qualification in the core enterprise in the supply chain to the upstream and downstream of the supply chain, strengthen the dominant power and control of the upstream and downstream enterprise, and improve the competitiveness of the whole supply chain, thus laying a favorable condition to adopt the acquisition mode to enter into the upstream and downstream. With the supply chain finance's comprehensive financing service on the upstream and downstream enterprise, the supply chain core enterprise selecting the transformation will be more smooth to extend the industry.

Impact of digital technology on Architectural Design Teaching

Fangda Yu

Hubei Engineering University, Xiaogan 432000, China

Key words: Digital architecture; digital technology; sketch thought; architectural design

Abstract. Modern education is dominated by the " rational technology "and pursuit the education of" rational technology ". Digital technology with hitherto unknown speed penetrated into many aspects of higher education, the formation of some cross fields, "digital architecture" is a typical representative. But the national universities course construction is relatively backward which is the cross course of architectural design and digital technology. The article analysis on the status of "digital building" and to discuss the innovation and integration of digital technology and construction courses.

Introduction

Modern education is dominated by the "rational technology "and pursuit the education of" rational technology" [1]. The architecture is an interdisciplinary science model, which relates to computer science, geography, environmental science, information technology, sociology, culture , arts, engineering, law, political science and even disciplines. With the development of information technology and learning theory, a theory and method can not simply rely on the classroom,but also can not simply use the traditional media, and should integrate different theories and methods.

Background of Research

With the development of digital technology, which occupy a certain position in the development of national economy, digital technology has penetrated into all walks of life, and become a kind of important means to capture the benefits of all walks of life. Building industry as a modern industrial, under the influence of digital technology has changed its use, especially in the architectural design, has been widely applied. It is self-evident, digital technology has become the main method of large modern architectural design, the organic combination of architectural design with digital technology, can make the architectural design of digital realization of great leap forward. At present, the application of digital technology in architecture design, so that the efficiency of architectural design has been greatly improved, and enhances the four-dimensional analysis (Fig. 1, Fig. 2). Moreover the design cycle and cost has improved, in this case, the interest is improved, but also more in line with the trend of socialization.

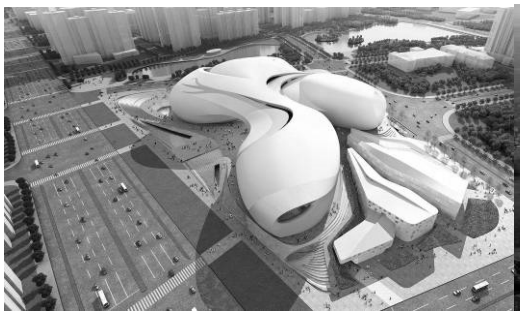

Fig.1

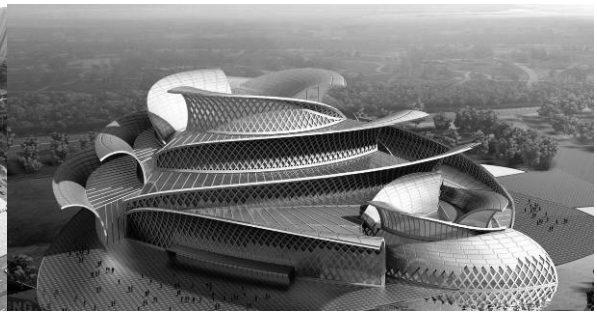

Fig.2

The status of digital technology integrating into Teaching

Digital technology integrating into the school teaching,which close the contaction of the education and the external world ,Improve educational efficiency .At the same time, the digital technology support on innovation teaching methods, speed up the implementation of teaching and learning in the way and idea innovation, so as to improve the traditional teaching mode is important significance.

In recent years, The modernization of education was promoted by the education informatization has become an important strategic measures for the development of education in china. Basic education is a development trend in the application of the integration of information technology and curriculum characteristics. At present, only about 10% of teachers into the advanced stage of the application of information technology to create a stage, most of the teachers still in primary technology application stage, the effectiveness of educational informatization should be further improved. Have a significant impact attitude, self-confidence, informatization teachers school environmental factors on Teachers' information technology into teaching behavior and different stages of integration.

From the practical experience, the digital technology is to Architectural design a lot of help, but the rise of digital technology for a short time, and there are not mature, so there are still shortcomings when used in architectural design. For example, digital technology is the lack of a unified standard, and the lack of qualified technical personnel, in addition to intelligent digital technology is very low. Therefore, the application of digital in industry and in architectural design should carry on the innovation based on the use.

The status of Digital Architectural Design Course

At present ,Most of the colleges in Architectural Education, still work digital technology as a tool for CAD tools or design, the real distance use digital technology into the architectural design, or use digital technology to integrate the whole design process is still a certain gap.

The teaching content of building digital technology including the use of methods, drawing, performance statistics, analysis, word processing, Internet softwares and programming knowledge, these knowledge in teaching from different courses. How to put the teaching and research of these knowledge around the building design together, to form a set of digital architectural design teaching system. [2]

In some colleges, the basic training of traditional design method has been greatly weakened because the advantages of digital technology in the construction aspect, ,design principle and design method of teaching weakened, premature low grade students to make the design and performance of digital tools, produced is not conducive to learning the basic theory and improve the negative effects of culture art accomplishment and professional quality. [3] Some design department is also reflected that some architecture graduates lack of knowledge and ability to solve practical problems, only with the computer now.

In the situation of the Digital technology rapid development , in the face of these problems, teaching need the method in the light of its general trend to solve the problem, the teaching reform of architectural design need to stand in the height of the information age, and gradually find out a way to adapt to digital architectural design teaching and the development of digital technology .

Curriculum integration of digital technology and architectural design

Architecture students must have high sensitivity to the graphics, image, color, lighting changes, building space and other factors, it is often the traditional teaching method was more difficult places, and multimedia technology can greatly enhance the students ability of thinking in images.

For beginners, the shape and the spatial construction is a difficult course of architectural design. In order to improve and cultivate the students' space thinking ability, at the same time the basic method can be focused on the elements, space design approach, combining the traditional teaching method, Introduce the three-dimensional computer and network technology. Namely, using a variety of media: textbooks, blackboard, teaching aids, video (VCD), slide, projection, CAI courseware, GIS technology, network media and other means to the storage, transmission and processing of information. Scientific arrangement of teaching processes and factors, to provide a good learning conditions for students, develop students' space thinking ability, drawing and interpret the images ability, improve the architectural design teaching effect. [4]

How to realize the benign transition from space elements to the teaching of architectural design, how to understand the design thinking and methods of the architectural design, which requires the reasonable architectural design teaching organization. Course design requires students to design a material form must be established on the basis of investigation and analysis, architecture design object should involve building elements and city elements, also should be the size and scale of the students can grasp in a short period of time. Design thinking should inherit architectural design training to obtain the logic thinking, image thinking and microcosmic thinking, rational thinking, but also expand the digital design of the comprehensive thinking and macro thinking.

The teaching of architectural design course requires students to form scheme based on elaboration of 3D model, the students can inspire the deep function of various software, after the spatial ability to set up is more complex, spatial thinking to the students can get rid of beam, to play the greatest degree. Such as the undulating slope or the base which in need of care or protection of surrounding retained buildings. The base simulation is established through the integration of transformation from field data, to balance and minimize earthwork. The sketch is to combine the objective and accurate digital perfect intuitive sense and the computer in a way. Although some sketches may not be accurate control in the figures, some design such as the master architect Frank Gehry, but is very helpful to direct architects creativity and the subjective intention, reflect the liquidity and other architectural characteristics, which itself has no digital limit accurate. [5] teaching can choose the computer design of the basic knowledge and various design system, arrange the computer drawing software design method of digital design, subjective and objective three attribute three attribute and the design of the physiological and psychological factor theory. And with"grasshopper" plugin of rhinoceros software, through changing the parameters, precise control of physical form. From simple method of traditional sketch thought hand-painted, extended to the surface and plane collocation and complex combination, focus on mastering their mutual complex configuration aspects (Fig.3, Fig. 4), describes a set of scientific, practical building design method, both rich emotional elements of architectural design the architectural design, and improve the scientific work efficiency, innovation for the modern education technology drives the course structure and teaching content.

Conclusions

Architectural design is also faced with hitherto unknown challenge Under push of digital technology, "digital architecture" is rebuilding the new ethics system FOR the architectural design in the process of immaterial and material. The teaching should be keen to adjust teaching strategies and the architectural concept, so to follow the trend of development.

Keywords: Landscape pattern; Haikou City; landscape index; land transfer matrix

Abstract. The article is studying on the Haikou city, using Remote Sensing technique and GIS technology, with ArcGIS, ERDAS, FRAGSTAS, analyzing the temporal and spatial variation of landscape in Haikou City from 2000 to 2010, drawing the conclusion: residents, construction, farmland and forest land is the main part of landscape pattern and increased rapidly. Besides the decrease of unused land and water area, it also reflects that not only the landscape fragmentation degree of the integral sight in Haikou City in relatively high, but the landscape fragmentation degree of the residents, construction, farmland and forest land, which are the main part of Haikou City , is also relatively high.. Besides, the data also shows that each landscape didn't connect well and the exchange of material energy among landscapes is not smoothly, which go against the mutual development between the landscape. However, the distribution of landscape in Haikou City is fairly balanced. There is no particularly advantaged type, which contributes to the balanced development of the landscape.

Introduction

Landscape pattern is landscape elements arrange and combine in the space. It also shows the landscape heterogeneity. The study of landscape pattern is the most important part of the research of landscape ecology. We can study the mechanism between land-use and landscape pattern change through the progress of landscape pattern change. By the research result, we can offer the basic research for the optimization in landscape pattern and sustainable land use.

Landscape pattern is one of the three core elements of the study in landscape ecology. It's also the base of the progress of studying landscape and landscape function. Landscape pattern usually means the distribution and combination rule of the landscape spatial unit (plaque) in different size, shape and nature reflected in the space. It is the specific performance of the landscape heterogeneity and the results of various ecological progress in various scales effects..

Landscape pattern index is a short of simple quantitative index that can highly concentrate landscape information and reflect the structure and characteristic. By the landscape pattern index, we can quantitative study landscape's characteristics, spatial arrangement and dynamic change. This article specifically selects some landscape pattern indexes as follows: NP, CA/TA, %LAND, LPI, IJI, PR, SHDI, SHEI and CONTAG.

This article used the remote sensing image date of Haikou City in 2000 and 2010. The data images are disposed by image geometric correction, mosaic, projection transform, clipping and fusion by using ArcGIS10.0 and ERDAS IMAGINE9.2 software. Based on it, we used ERDAS IMAGINE 9.2 to radiate the image and enhance the space, improving the quality of the image. And then, we used the method of supervised classification to sampling, establishing classification modules, interpreting images and evaluating the accuracy. Then we concluded two phase current land landscape pattern in Haikou City by analyzing. After that, we calculated the landscape pattern index by using ArcGIS10.0 and FRAGSTATS4. We analyzed the change of the landscape pattern in Haikou city by analyzing two phases of image data and calculating the landscape index.

Study Area

Haikou city is located in north latitude 19 ° 32 ′ -20 ° 05 ′, longitude 110 ° 10 ′ -110 ° 41 ′, located in the northern part of Hainan Island, Flat terrain, slightly heart-shaped.landscape basic is divided into the northern coastal plain, central order along the Yangtze river region, eastern, southern tableland, lava in western region; East from DaZhiPo old town village, west to west township south village, 60.6 kilometers distance, South from Dapo Town five car Village, north to the sea, 62.5 km distance, the city's land area of 2304.84 square kilometers. Haikou city is located in the low latitude tropical edge, belongs to the tropical maritime monsoon climate, annual sunshine time is long, the radiation energy is large, the average annual sunshine hours 2000 hours, solar radiation can be up to 11 to 120000 Card, annual average temperature 24.2 ℃, annual average rainfall of 1684 mm, the average annual evaporation is 1834 mm, the average relative humidity is around 85%, southeast and northeast wind is given priority to all the year round, the annual average wind speed 3.4m/s;north Linhai, sea area of 830 square kilometers,a coastline of 131 kilometers , sea water average temperature 25 ℃

The Research of Landscape Pattern Change of Haikou city from 2000 to 2010

We analyzed the land-use transfer matrix of Haikou city in 2000 and 2010 by using ArcGIS10, obtaining the data of two phase of land-use transfer matrix of Haikou city in 2000 and 2010, follow the table 1.

Table 1 Land use transfer matrix of Haikou city in 2000 and 2010 unit: Ha

2010 / 2000	Settlement and construction land	Unused land	Arable land	waters	forest land	in total
Settlement and construction land	-	16.44	123.38	7.44	66.85	214.11
Unused land	263.44	-	385.6	2.15	211.61	862.80
Arable land	237.7	59.96	-	5.85	221.26	524.77
waters	103.08	10.37	47.25	-	28.66	189.36
forest land	221.63	32.67	388.54	0.82	-	643.66

From table 1,it can be seen, in 2000,the land use type of Haikou city, the transformation of unused land area is the most, followed by the cultivated land and forest land, and transformation of water area at least. Among them, the unused mainly converted into residential areas, cultivated land and forest land and construction land, be transferred to the water area is less; Cultivated land mainly transferred to cultivated land, forest land and settlement and construction land; Woodland mainly transferred to cultivated land, forest land and settlement and construction land, which can also explain in 2000 the cultivated land, forest land and residential areas and the construction land area changes in Haikou city large, and growth tendency. From the perspective of the land use type of 2010, settlement and construction land mainly come from the unused cultivated land and forest land from the 2000 years, cultivated land mainly comes from the forest land and unused land and farmland from the 2000 years, forest land mainly comes from the cultivated land, forest land and unused land..

First, by using ArcGIS10.0, we transferred the two raster data classification results of Haikou city in 2000 and 2010 into GRID raster data. Then we calculated the landscape pattern index which has selected by using FRAGSTATS4.0. Calculation results are shown in table 2 and table 3.

Table 2 Calculation result of landscape pattern index of Haikou city in 2000 and 2010

Index / Land type	NP		CA		%LAND		LPI	
	2000	2010	2000	2010	2000	2010	2000	2010
Settlement and construction	240932	50456	17258.74	76872.06	7.65	34.07	0.44	13.31
Unused land	234320	22523	28503.32	7799.67	12.63	3.46	0.54	0.05
Farmland	86253	35167	126958.39	85085.01	56.27	37.71	42.91	11.44
Water	71090	7501	19258.40	6130.98	8.54	2.72	4.27	0.28
Forest	249092	52009	33635.39	49724.73	14.91	22.04	2.92	0.62

Table3 Calculation result of landscape pattern index of Haikou city in 2000 and 2010

Index / Year	NP	TA	LPI	IJI	PR	SHDI	SHEI	CONTAG
2000	881687	225614	42.91	74.13	5	1.275	0.792	30.59
2010	167656	225612	13.31	60.87	5	1.282	0.797	29.55

Through two transverse comparisons of data in Table 2, it can be seen that residents, construction, forest land and farmland is increasing rapidly, whereas unused land and water area is decreasing rapidly. In addition, residents and construction's increase speed is the largest. In the proportion of the whole landscape, it increased from 7.6497% in 2000 to 34.0726% in 2010. And unused land's decrease speed is the fastest. In the proportion of the whole landscape, it decreased from 12.6337% in 2000 to 3.4571%in 2010. What's more, by the LPI of various landscape, it can be seen that except the maximal plaque of resident and construction's proportion of the whole landscape increased rapidly, LPI of other kinds of landscape are all seem to decrease, which indicates that due to the development of the city, Haikou city's land area of residents and construction increased rapidly from 2000 to 2010.

Table3 shows the whole landscape pattern of Haikou city to calculate the landscape pattern index of Haikou city and analyze the change of landscape. As for NP, the number of 2000 is much larger than the number of 2010, which indicates the fragmentation index of the whole landscape pattern of Haikou city in 2000 is fairly large and the landscape is more fragmentized than 2010's. From the CA of two periods of data, it can indicate that the area change of Haikou city from 2000 to 2010 is not large. Compare the LPI to table 2, it indicates the advantaged type of Haikou city in 2000 and 2010 is farmland, residents and construction. What's more, the future social and economic activities in Haikou city are mainly based on residents and construction. IJI can be used to show the overall spread and tied in plagues. In 2000, IJI is 74.1287 and in 2010 IJI is 60.873, which shows that the connected and approaches conditions among each plague in 2000 is better than 2010's. However, both data are not large, which means on the whole, the connection among the landscape of Haikou city is not well. The connection and communication among the landscape are not well smooth. What's more, the number of CONTAG indicates that there is no well connection among the landscape, and the degree of fragmentation of the landscape is still rather high. Both SHEI and SHDI are used to compare the index of diversity change in different landscapes or the same landscape in different times. From the data in table 3, it can be seen that various landscape types in Haikou city distribute equally and there is no landscape has apparent advantage type.

Conclusion and Prospect

From the analysis above, it can be seen that Haikou city from 2000 to 2010, with the rapid development of economy and the improvement of people's living standard, especially the boom in the tourism of Hainan province and Haikou city and the construction of Hainan international tourism island in recent years, it made the landscape pattern in Haikou city changed apparently. From 2000 to 2010, in the land utilization type of Haikou city, the area that unused land transferred into other land type is the most, the next is farmland and forest land, the smallest area is water area.

In the land utilization type transferred from unused land, there is mainly residents, construction, forest land and farmland. Besides, in the land utilization type of Haikou city in 2010, the area in residents, construction, forest land and farmland increased relatively large. It also indicates, from 2000 to 2010, there are mainly the increase area in residents and construction and the decrease area in unused land. In the landscape, residents, construction, farmland and forest land are the main part of landscape and increased rapidly. Besides, unused land and water area decreased rapidly. It also shows that not only the landscape fragmentation degree of the integral sight in Haikou City in relatively high, but the landscape fragmentation degree of the residents, construction, farmland and forest land, which are the main part of Haikou City , is also relatively high. What's more, the data also indicates that there is no well connection among each landscape and the communication of material energy among landscape is not smooth enough, which go against the mutual development between each landscape. Nevertheless, we can also see that various landscape types in Haikou city distribute equally and there is no landscape has apparent advantage type, which help the harmonious development between each landscape.

Keywords: Information Disclosure; Reliability Model; Workflow

Abstract. This paper presents a public information platform based on reliability coefficient for information disclosure process in construction field. In this platform, we constructed a model of enterprise reliability coefficient and enterprise credit evaluation system, unified credit standards of Shandong Province in the construction industry sectors. Meanwhile, we adopt flexible workflow to definite workflow model of public information platform and using SOA architecture which is service-oriented and object-oriented programming ideas to realize the entire system. Finally, the article analyzes the public information platform in the field of engineering construction in Shandong province, and after the test run, the results show that the system has better scalability, stability and high security.

Introduction

Project information and the construction of credit system in the construction field are major decisions made by the central on the basis of reality. In recent years, construction field are prone to corruption mostly associated with the project decision-making, the approval authority and capital management is not open and transparent. Establishment of project information disclosure system and the integrity of our security mechanism in the construction field is an important way to solve the construction information is not open, transparent, market entry and exit mechanism is not perfect from the system, and which is an important part of controlling corruption from the source. Promoting the construction project information disclosure, is to promote the construction field projects to accept supervision under the sun, and is an important measure to prevent the occurrence of corruption, Which is an important measure to ensure implementing the "Regulations on Open Government Information", protecting the people's right to know, to participate and to supervise, and the construction of socialist democratic politics.

According to the requirement of central commission and Shandong province for discipline inspection, information disclosure and credit system construction work in Shandong Province construction field projects has already started. It requires all levels of departments to adjust measures to local conditions and make full use of the internet and all levels of government websites focus on disclosure of information to avoid redundant construction and waste of resources. Making information disclosure and credit system construction can be combined with commercial bribery governance, social credit system construction and other work to promote mutual.

Shandong province puts forward the development and construction of project information and credit information sharing service platform in Shandong construction field. Combined with the basic project information and basic credit information guiding catalogue, and depending on business workflow, it further refinement of project information and credit information collection,

publication, management and use, reached to strengthen the industry regulator and gradually achieve full coverage of all kinds of information on construction engineering and establish credit files for businesses and individuals. Insist on the principle of openness, fairness and justice, honesty and credit, it can promptly publish all kinds of specification information related to the construction field.

This paper takes information sharing service platform in Shandong province construction field for example, analyzed the information publicity business process and system architecture in the construction field, and accordingly proposed a model based on the reliability coefficient. The research in this paper has certain academic significance and application value.

Credit reliability model definition

(1) Engineering credit status

Currently, the engineering involves transportation, water, construction and other industries. All levels of the industry departments are responsible for detecting credit behavior of the main local area parties involved in the construction and collect, audit, record the credit information of the business units and personnel in the construction activities according to the unified credit information management measures in the industry. Employees with a different unit or qualification of employees in different sectors identified, which resulted in the inter-industry mutual recognition of credit information sharing difficult. The paper puts forward the innovation of using the reliability coefficient model, construction field credit system, unified trade credit standards, credit information sharing among industries.

(2) Credit reliability model definition

To quantitatively describe enterprise credit in the engineering field and definite enterprise credit reliability calculation model, the calculation steps of the model is just as follows: 1) Obtaining the main factors affecting the enterprise credit through principal component analysis method and noting for S^1, S^2, …, S^n. 2) Random inviting m groups of experts to rate these factors, scores were recorded as d^{11}, d^{12}, …, d^{1n}; d^{21}, d^{22}, …, d^{2n}; …; d^{m1}, d^{m2}, …, d^{mn}. 3) Because each factor has different dimensions, so the results of each factor score was normalized, and then calculate each factor of the arithmetic mean value, the calculation results denoted as: X^1, X^2, …, X^n. 4) Calculate the product of each factors and the corresponding weights according to the weight set, the result is marked Y^1, Y^2, …, Y^n. 5) Taking into account the experts may have uncertainties subjective or objective factors in the process of scoring, in order to reduce the influence of uncertain factors. First of all, equivalent normalization processing results of Y^1, Y^2, …, Y^n to make Y^1, Y^2, …, Y^n obey the standard normal distribution asymptotic. Secondly, set the same confidence level a of enterprise credibility, and then obtain business confidence interval according to the theory of confidence in Statistics. Finally, complete the quantitative analysis and grading of enterprise reliability according to this confidence interval.

Design of Information disclosure process

(1) Information disclosure process introduction

Taking the project as center and approval process as the main line, accordance with the principle of "who is in charge, who released", project management units need to do a good job of information collection, release and maintenance, etc. Project approval authorities collect, review and publish project approval, filing and other related information. The project construction units provide project management and key staff behavior information and the department in charge of the project review and issue this information according to the management authority. Land and resources departments collect, review and release the information of land use rights, mining rights approval and transfer. Basic information of related companies is disclosed by the competent authorities in accordance with the enterprise registration functions. Basic information of related enterprise qualification and personal qualifications is disclosed by construction quality management according to the functions.

(2) Workflow engine design

The workflow engine is responsible for the interpretation of the process definition and controls the operation of the process instance. Information release process using the simplified workflow engine takes each workflow execution engines package into a Web Service interface. These interfaces include: 1) Process Definition: responsible for the interpretation and instantiate a detection workflow; 2) Monitoring Tools: responsible for status monitoring of active and inactive process flow, version management, process management and business process statistics; 3) Workflow client applications: responsible for receiving and feedback the client application requests; 4) other related services interface: the interface includes a document printing, view, data summary printing and other related services.

In the workflow management platform, a plurality of workflow engine cooperative work to promote the execution of a workflow instance. Each workflow engine is responsible for part of the active control and management in a process and calls the relevant resources and application tools to complete the implementation of these activities. Between each workflow engine and workflow engine and user interface using SOAP messages for interactive. Information disclosure process adopts simplified workflow engine, and the design is shown in Figure 1.

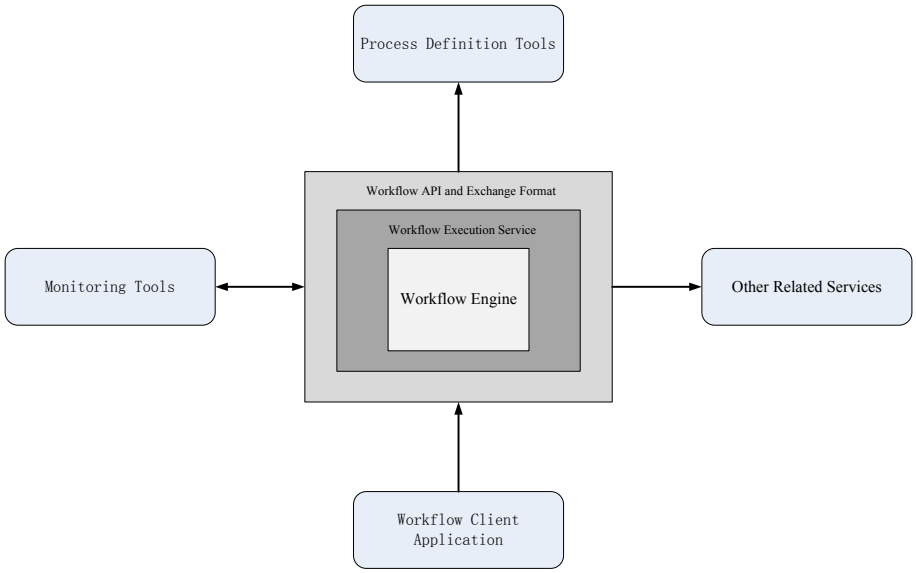

Fig.1. Workflow engine design

Design and implementation of system architecture

The design, development, deployment and testing of project information, credit information sharing and information exchange platform in Shandong province construction field are all in cloud platform of Shandong province cloud computing center. This platform is based on B/S technology architecture, using .NET framework coding, and application server uses authorized by Microsoft Windows 2003 Server, the database used SQL Server 2005 above which is authorized by Microsoft. Our goal is aimed at building a secure and reliable large-scale integrated management information system adopting a unified data exchange, unified interface standard and unified security.

The entire platform system architecture is based on advanced multi-tier architecture model and the MVC (Model-View-Controller) pattern. Some applications can be built by multi-tier architecture which has features such as loose coupling, easy to reuse, scalability. In addition to facilitate the organization and implementation of software development, it can also facilitate system maintenance and expansion in the future. In the MVC pattern, Model component encapsulates the kernel data and functionality, so that the core functions are independently of the output representation and input, and view component obtains information from the model displaying to the users. Through the mutual separation of model, view and controller, which makes the development of frame can be flexibly adapt to changing requirements of the function of user interface.

System from the bottom to the main frame is divided into three layers: the data tier, business tier (divided into application support tier and application tier) and the presentation tier (divided into client tier and presentation tier). The overall architecture of the system is shown below in figure 2.

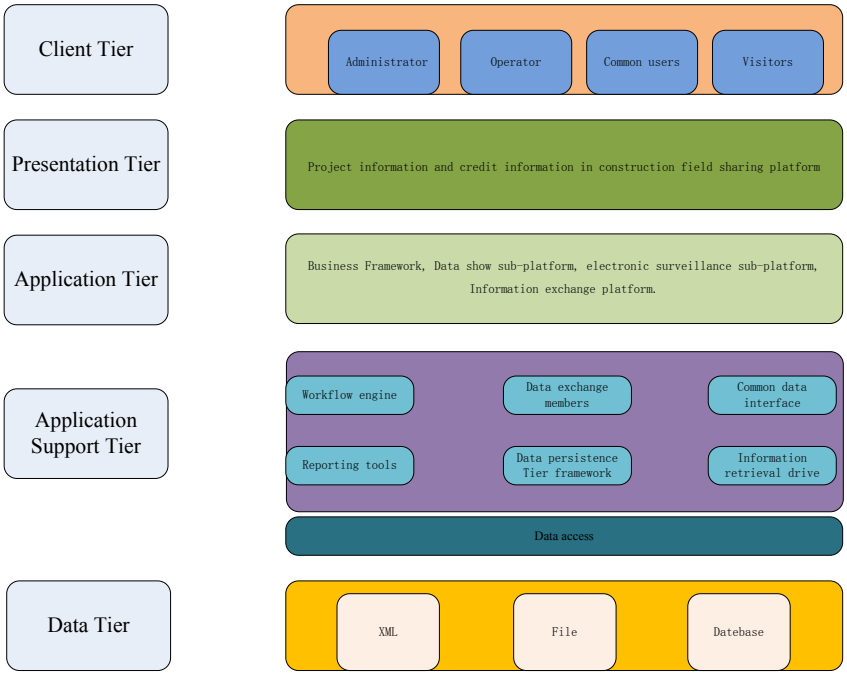

Fig.2. System Architecture of Information disclosure platform

Instance analysis

Project information and information sharing service platform of Shandong province engineering construction field has started to run in December 2013. The information platform in accordance with the requirements of Shandong province commission for discipline inspection and project information disclosure and credit system construction work coordination group in Shandong province construction field. The information platform in accordance with the commission for discipline inspection of Shandong province and the provincial engineering construction project information and the requirements of good faith system construction work coordination group, further combed information disclosure processes in Shandong construction field and improve the standards of information released. All business functions are running on the line, and the program runs very stable. In particular, this paper innovatively proposed the use of reliability coefficient model and building engineering credit system, unifying industry credit standard. This is also the major initiatives in the anti-corruption which focus on the prominent problems in the field of construction management in Shandong province.

Conclusion

Based on information disclosure in engineering construction field as the breakthrough point, this paper presented a designing scheme of public information platform in the field of engineering construction based on reliability model and innovatively proposed the use of reliability coefficient model and building engineering credit system, unifying industry credit standard, sharing industry credit information. Using a simplified workflow engine makes the system easy to build and using service-oriented architecture SOA and object-oriented programming ideas for system implementation solves the construction field of information disclosure shared problems. From the design example of Shandong province engineering construction field of information disclosure, we got satisfactory results after test run. Next, we will further optimization in the design of reliability model.

The Research on Statistical Characteristics of China Civil Aviation Network

Hongguang YAO[1]

[1]School of Air Transportation Shanghai University of Engineering and Science

Shanghai, 201620,P.R. China

email:Yhg1yhg@sina.com

Keywords: Statistical Characteristics, China Civil Aviation Network, complex networks

Abstract. Aviation network as an important infrastructure, play a huge role in social and economic development. There is a close relationship between the efficiency and its network structure. In this paper, navigation of the 163 cities and 2198 air routes network composed of analysis the statistical characteristics of the empirical analysis, the basic structure of our aviation network properties.

An overview of China's aviation network

The number of routes and the coverage is often used as a measure of a national air transport network an important indicator of the level of development. In recent years, China's rapid economic development has greatly driven the development of the domestic air transport, navigation and route number of cities are growing rapidly. By 2010, China's domestic routes 2198 (not including Hong Kong, Macao), shipping more than 163 cities, covering the initial formation of the major cities in the domestic air transportation network. However, the uneven distribution of the density domestic routes, the East Mississippi condition sparse and not with the number of shipping routes to increase the airport has changed.

Been expanding at the same time, the efficiency of the existence of low air network, the network had no obvious effect of economies of scale and other issues. The main reason is, whether airlines or the CAA during the route planning is usually only one route open route the demand analysis as the main index, but not on the new route synergies with existing networks for analysis, ignoring the air Network integrity. Overseas experience shows that with the constant expansion of aviation network, the potential economic advantages of scale increasingly huge. Through the analysis of airline network structure, help to optimize the aviation network structure, improving the efficiency of air transport.

China Civil Aviation Network data acquisition

The Tourism Net boat class timetable as the main source of data, by the end of May 16, 2011, a total acquisition navigable City 163, 2198 domestic routes, flight 9611.In 163 a navigable city respectively as a matrix of rows and columns, with two flights between city as weight, forming a 163 * 163 weighted aviation network adjacency matrix. Using the matrix, to be navigable city in aviation network important degree as the standard, obtains the Chinese aviation network navigation city social structure. More important is the closer to the center position, indicating that the navigable city in aviation of the importance of the network more and more strong.

Chinese aviation network statistical analysis

①Degree and strength

Degree of node and node is defined as the total number of border. In the aviation network, a node of the city of greater means connected with the city number, it has few routes are also more. The flight number is a measure of the importance of node city key factors, only through the "degree" of value is not enough to reflect the importance of node city[1]. Therefore, the node degrees

corresponding to evolve into another parameter, strength, in order to reflect the city node in the aviation network status, defined as:

$$s_i = \sum_{j \in N_i} w_{ij} \quad (1)$$

Wherein N_i represents a node i neighbor sets ; W_{ij} said node i and node j arc weights that nodes i and j city node between JAL class number.

In this paper the application of the University of California at Erwin (Irvine) scholars prepared free of large scale network analysis software Ucinet calculation of the Chinese 163 navigable city degree and the point of the right, the top 20 spots in the city as shown in Table 1.

As you can see from table 1 degree and strength before the 20 city with a high degree of overlap, shown in China has the most course of 20 city is as JAL class number 20 city. China's aviation network point intensity distribution is obviously divided into two parts, in the point strength = 57 bend, obeys a power-law distribution. At present, China has 2198 domestic routes and flights of 9611, ranking the top 20 City flights accounted for the proportion of the total number of the flight reached 52% and 68%, China air transport resources distribution not balanced, large and flight routes are concentrated in a small city. [2]

Table 1 The navigable City moderate top 20 city summary table

Rank of Degree	city	Degree	strength	Rank of strength
1	BJS	118	809	1
2	CAN	96	498	3
3	SHA	95	676	2
4	CTU	68	390	7
5	KMG	67	400	6
6	SZX	66	455	5
7	CKG	63	307	8
8	XIY	62	479	4
9	XMN	52	281	9
10	CSX	46	208	16
11	DLC	44	191	17
12	NKG	43	212	14
13	HGH	41	272	12
14	WUH	40	211	15
15	TAO	40	260	13
16	TNA	40	221	14
17	URC	39	183	18
18	KWE	39	154	22
19	SHE	37	156	20
20	CGO	36	153	23
Total		1132	6516	

②Aviation network average shortest path

The shortest path is defined in the network two the distance between nodes, which connected the two nodes of the shortest path contains the number of edges ; the average path length refers to all nodes in the network between the average shortest distance, it can be used to measure the transmission efficiency of the network[3]. In the aviation network, city of between the average shortest path, can reflect the passengers from one city to another city to average at least the number of transit, reflect the aviation two nodes in the network city travel convenience. The whole network average shortest path is calculated by the following formula type (2). [4]

$$L = \frac{\sum l_{ij}}{\frac{1}{2}N(N+1)} \quad (2)$$

The application of Ucinet software and data matrix, the calculation of Chinese aviation network average shortest path 2.16.From our country an arbitrary navigation based on average only need a transit can reach other navigable city.

In Chinese aviation network all possible travel routes, direct route accounted for only 8%, while the longest path is 4, namely the need to transfer 3 times. Need many transit navigation city are mainly distributed in the periphery of Figure 1, in the whole air network is relatively important

position, for example, if the program from Xinjiang Akesu to Guangxi white, subject to Urumqi and transit of Chongqing, after the 3 transfer to reach the destination of Baise.

Dielectric and dielectric number distribution

Betweenness refers to all nodes in the network of the shortest path through the point ratio, a node betweenness can reflect the nodes in the network's influence. In the aviation network, a navigable City referred to a number of larger shows the city transit of ability is more strong, the aviation network plays more and more important. The application of Ucinet software and data matrix, calculated 163 navigable City dielectric numerical, referred to the number of top 20 city are shown in Table 2.

Table 2 Betweenness to the number of top 20 city summary table

City	BJS	CAN	SHA	URC	XIY	KMG	CTU
Betweenness	7411	3460	3430	2417	2391	1909	1478
City	CKG	KWE	CZX	HRB	HET	XMN	CSX
Betweenness	1395	1113	917	541	389	368	349
City	KRL	DLC	CGO	WUH	SJW	TAO	
Betweenness	322	257	227	208	198	183	

Through the calculation shows that the current Chinese 163 navigable City referred to the number of differences and disparities, Beijing referred to the number 7410.88 ranked the first, and 79 navigation City referred to the number of 0, as shown in Figure 1.Show all navigable city in China in nearly half of the city is still cannot play the transfer function.

As aviation network two key statistical indicators, referred to the number and strength are closely linked.163 navigation City referred to the number and strength of relationships as shown in Figure 2 below, whole betweenness basically with the level increases, but there are many little deviation from the straight line, fall on the line below. This referred to the number and strength has a certain connection, but not strictly obey the known power-law function relationship. Some high strength city are mainly distributed in the municipality directly under the central government, provincial capital (capital) and some important province city, such as Xiamen, Qing Dao ; and referred to the number of high city in addition to the city, also includes a number of important regional transport hub such as Urumqi, Korla and so on. The above suggests that in Chinese aviation network has more routes, a multi-day flight navigation city often is a network of important transit hub ; in addition some navigation city routes and flights although the amount is more limited, but still in transit network plays an important role. Has a high strength and referred to the number of navigation city is Chinese aviation network key nodes in the network communication plays an important role. [5]

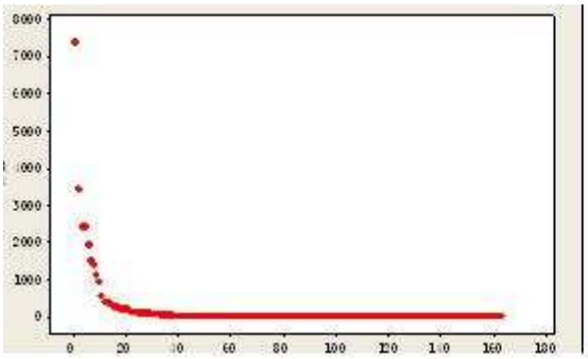

Fig 1 Navigable City betweenness distribution map

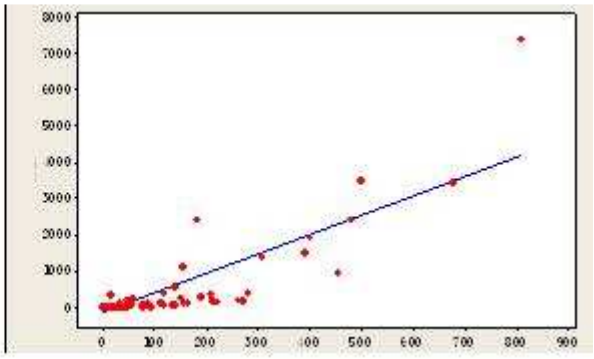

Fig 2 Navigable City referred to the number and intensity of scattered diagram

Conclusion

aviation network has the following properties:

(1) With the increase of flights, passenger throughput does not increase linearly, but rather to increase exponentially. This can be used in economics to understand the network externalities, the more the route connecting the airport, people are more willing to go the airport, because in this airport, either direct or transit is more convenient, there are enough Flights to choose from, can save the transit waiting time.

(2) from any airport in China, to any other airport, the average require only one transfer. Direct flights can be accounted for only about 9% of flights. The longest path is 5, that requires transit 4.

(3) between the nodes can find a shorter path connection from the network as a whole, the small-world network polymer layer also has large coefficients and small average path length of the statistical characteristics of the two. China's aviation network from the high polymer layer coefficient and the relatively short average path length of the term, it can be concluded, China's aviation network is a small world network.

Keywords: Digital exhibition-design;Henan Province, Virtual reality;Geological museum

Abstract. The digital technology has been brought a profound social change to human, especially in the digital display technology. In order to explore the application of Digital exhibition in geological museum field, the author applies by the "building roaming + picture + text" way to the audience on the Architectural layout and displayed content of Henan Geological Museum, not the traditional construction roaming form, according to the "Henan Provincial Geological Museum exhibition design" case.

Introduction

In recent years, with the development of computer technology, digital media technology have made a spurt of progress, especially digital exhibition combining with computer technology has gradually become the new subject field of display design. Nowadays, digital exhibition hall has broken through the traditional exhibition wall, showcase, making it more interactive, comprehensive and strong sense of the scene. Existed display mode of Henan Province Geological Museum: Exhibiting through the floor structure, caused by too tight space layout, make the geological nature mood lost. In order to make the Geological Museum of Henan province reached the level with harmony, high-tech, unique to Henan, and to explore how does the Digital Media technology apply more effective in exhibition design museum of geology. The author uses the following creative ideas in this work.

1. Scattering with original hall. The original ore forest and mineral hall merge into ore mineral hall. The dinosaur hall, ancient elephant's hall and ancient life evolution hall merge into paleontology Hall. The original lobby becomes into entrance gate of the geological museum, Mineral resources hall, geological environment hall and earth hall are unchanged, Cinema 4D dispersed in all inside. It is convenient for reasonable arrangement of all exhibition halls, expanding the exhibition's area, achieving grinding, strong attraction and integration of the natural effect.

2. Designed separately each exhibition hall, making its architectural style independently. This can prevent phenomenon of "the crow black".

3. Applies by the "building roaming + picture + text" way to the audience on the Architectural layout and displayed content of Henan Geological Museum.

Caption 1 -- "Henan Provincial Museum of geology"

Caption 2 -- Geological Museum of Henan province is located in the Jinshui District of Zhengzhou City, the museum consists of five exhibition halls, including: the earth hall, paleontology Hall (ancient dinosaur hall, hall, the evolution of life hall), Ore mineral Hall (ore hall, minerals hall), mineral resources department, geological environment Hall.

Caption 3 -- " Henan geological Museum -- touch the history of the earth, staring at the essence of nature. As is shown below the hall's design of Henan geological Museum , roughly the shape using the arc, the column top designed 'Globe' appearance, in front of the small garden around the 'geological Hammer' sculpture, permeated with the subject of 'geo'.

Caption 4 -- mineral resources hall, it shows mainly the main mineral resources and the mineral resources economic Henan province

Caption 5 -- ore mineral hall, including ore hall and minerals hall, mineral hall main display hundreds of mineral crystal, jade specimen, enjoy the nature spirit; ore hall mainly display typical ore in Henan province found.

Caption 6 -- paleontology hall includes dinosaur hall, ancient elephant's hall and ancient life evolution hall. Dinosaur hall main display Mesozoic overlord -- dinosaur; Ancient hall mainly display the characteristics of Henan Province -- the Yellow River basin is Kingdom of the ancient Elephant ; The evolution of life hall adopts a double helix structure, describes the earth life growing out of nothing, from low to high evolutionary process to everybody.

Caption 7 -- geological environment hall, the halls area is smaller, but which still would be enjoy the rich geological resources remains in the Central Plains of China, understudied the function of geological environment for human survival and health, social development and progress of civilization; known geological environment and mass, and thus learned to live in harmony with nature or the geological environment

Caption 8 -- the earth hall, mainly introduced relevant knowledge of the universe and the earth to everybody. It includes eight planets of the solar system; various rock from the geological formation; influence of weathering, Karsts landform and glacial on human beings; the characteristics of Henan -- the Yellow River, loess, the Yellow River culture.

Caption 9 -- "looking forward to your visit Henan Geological Museum", "producer: Jianshe Wang", "end".

Product steps

3.1 previous preparation Collect Geological Museum exhibition design related on materials, such as works, documents, materials, textures, background music, picture and so on. Be familiar with the geological museum exhibits typical case. Sort and deal with materials in the "Adobe Photoshop cs4", such as three-dimensional materials and textures, seamless textures etc..

3.2Make 3D model Hall According to the pre-collected material and the demand analysis, then make 3D model of Henan Province geological Museum. It includes that a door, paleontology hall, ore minerals hall, mineral resources hall, geological environment hall, earth hall and the overall layout. Concrete steps will not go into here.

3.3Make 3D animation of exhibition hall According toTable2.1,and then make 3D Animation of museum displayed hall. Because concrete steps of making roaming animation are basically similar to each displayed hall of Geological Museum, making concrete steps to "make and render the whole animation" as an example. The other part of those is not much.

No.1 Make and render the whole roaming animation

Part 1 Product and render browsing animation of the overall layout

1) Using 3ds max 2010 to open the scene file named "overall layout.max".
2) Set the time arrangement for the 500 frame, PAL format. Parameters of time configuration are shown in Figure 3.1.

Fig. 1 Time configuration

3) Create three target cameras, used as making camera animation and key frame animation.
4) Choose a camera, then adjust the camera so that the screen at the door of geological museum in accordance with the animation overhauling script.
5) Set key point, moving camera overall and make image alignment to Central Avenue intersection.
6) Rotate camera, then move the focus of lens, and align inside the gate of the geological museum, set key frames at last.
7) Change focal length of the camera, set animation.
8) Turn off the key frame, browse the whole animation, and adjust little according to the animation effect.

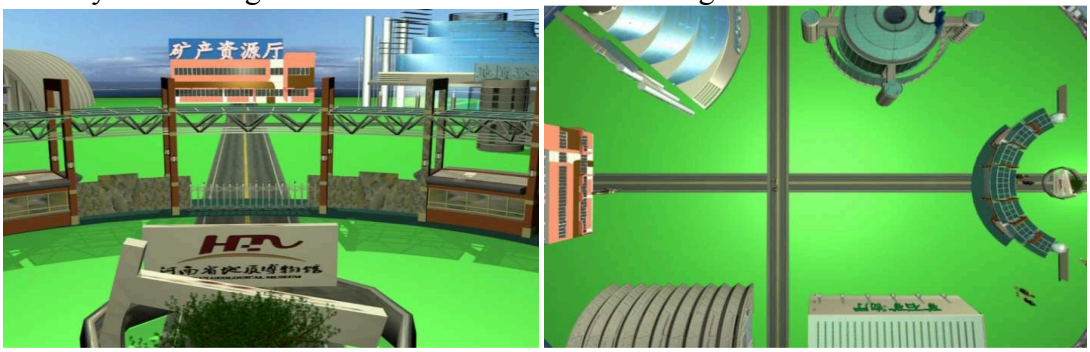
9) The animation rendering settings.

Part 2 Product and render animation of the bird's eye view.

1) Make the translational animation of the camera along Central Avenue by choosing a target camera in accordance with the animation overhauling script.
2) Make the path animation of bird's eye view by choosing a target camera in accordance with the animation overhauling script.
3) Render three camera animations as image frame sequence form, namely the file as “bird’s eye view.tga”.
4) Save the source file.

3.4Post digital compositing and editing we can carry out later digital synthesis and nonlinear editing after completing previous preparation and middle of the production. We should be strictly in accordance with the animation overhauling script in the process of digital synthesis and the final video editing at this stage. First of all, rendered image sequence frame file in the “3DsMax” import in “After Effects” and sub layer. Then make titles and joined the lens appropriate transition effects. Make and render output the final transition and transition effects in Premiere.

3.5The test run Make sample and timely be communication with customers after rendering the works, at last system testing. Animation effects as shown in Fig.



(a) Museum foyer (b) The overall layout

Fig. 2 Key frame of animation

Conclusion

We display successfully on Henan Geological Museum hall by 3D animation in the case. We combine with the use of "3DsMax + After Effects + Premiere" three kinds of digital media mainstream software in the process of production. However, the application of digital exhibition design in geological museum display field is just unfolding. We not only need to master the technology of computer software, but also understand geology; it said by composite talent. So it needs those people to explore and unremitted efforts.

Application of Information Visualization in Museums' Display and Design

Jieming HU [1, a]

[1] Donghua University, Shanghai 200051,China

[a] edu163819@163.com

Keywords: Museums, Exhibition and design, Information visualization

Abstract. Information visualization is more inclined to two-dimension design in traditional design field. As known to us all, it is unable to be applied in three-dimension. However, with the rapid development of design science, a growing number of people who are engaged in design have found that the application of information visualization can't be only restricted to graphic design as graphic design is gradually crossing with space design.

Museums' display and design is part of display design. And long time of exhibition is the main character differing from the temporary exhibitions. As the chief carrier of mankind's cultural heritage, museums are visited and browsed by people and finally realize information's expression, acceptance and cognition. In this process, information is visualized.

Background of this subject

Museums are the main carriers of culture and thoughts, sites of collecting, demonstrating and protecting mankind heritage as well as diary notes recording the development of human civilization. In addition, museums also shoulder responsibilities of popularizing public culture and providing visitors a relaxing and vivid atmosphere. Most importantly, display and design of museums have been a vital symbol measuring national economic and civil level.

With the rapid development of economy, people's material life standards have been largely increased. Therefore, museums have been the most favorable sites for people to entertain and meet their spiritual needs.

Museum display is an art of well connecting visual language with display space. People's needs for museums are never restricted to information but more about visual enjoyment.

Museum display and design is a comprehensive subject in the field of art of design, involving the crossing of a great many other subjects such as museum study, literature, aesthetics, optics and psychology. As far as I am concerned, based on such a background, research on the application of museum display and design will be pragmatic and promising in the near future.

Concept of information visualization

Just like mankind's language, information visualization, a kind of visual language, must abide by some special grammars and their own laws. In museum display and design, the visual language is indicated through some detailed media such as exhibition plates, light boxes, slides and simulation models. Whether the visual language is used properly and accurately decides the efficiency of information's spreading.

In addition to visual elements and visual grammars, the features of visual language ought to be focused at the same time. In display and design, visual language will work better than any other language and six requirements including visual cognition, legibility, accuracy, nationality, and contemporary characters must be satisfied.

Another important concept in information visualization is opaque setting. Below is a formula calculating the density of the distance from the items displayed from the visitors.

$$\rho_i = (N_{il} + N_{ir}) / (N_{/\max} + N_{r\max}) \qquad (1)$$

ρ_i is the density, N_{il} is the number of all points in the left space and N_{ir} is the number of all points in the right space. $N_{l/\max}$ and $N_{r/\max}$ are respectively the amount of data in both left and right spaces. Moreover, formula (2) will also help calculate the density.

$$\rho_i = n_i / \sum_{k=0}^{m} n_k \quad (2)$$

Obviously, calculation of density will help shorten the distance between visitors and the item displayed, giving full play to information visualization.

Influence of museum's environment on information visualization

Information visualization is an indispensible part in the display space. However, information visualization is impacted by space area and building height.

3.1 Spatial scale on information visualization

Visual language's existence depends on spatial interface which directly affects the corresponding tempo. The larger the spatial scale is, the longer visitors' observing distance will be. Therefore, spatial scale must be taken into consideration while designing the visual language.

The size of space to some extent decides the size of words. The bigger the size of space is, the bigger words should be set in bold. To take unit specification for example, based on the normal spatial distance 1000mm to 1500mm, the smallest specification words in the layout should be no smaller than 36pt as smaller words will make it more difficult for readers in the process of reading. If the spatial distance is added to 2000mm, the smallest words should not be lower than 48pt. However, in the small specification plates which should be read in close distance, it is acceptable to restricted the size of words within approximately 24pt.

To draw a conclusion from what has been claimed above that the size of words is supposed to be in proportion to visitors' observing distance. According to daily working experience, the relationship between observing distance and suitable size of words can be concluded through figure 1.

Observing Distance	The Smallest Word Size of Headline's Words	The Smallest Word Size of Explanatory Words
1000mm	72pt	36pt
2000mm	110pt	48pt
3000mm	150pt	72pt
4000mm	200pt	90pt

Figure 1. Relationship between observing distance and word size

3.2 Influence of light on information visualization

Light plays a vital role in museum's display and design. The majority of museums' light made in an artificial way. However, currently, a growing number of modern museums are in favor of natural light in view of energy conservation.

Most of the natural light in museums' display and design space is brought in only in the public places, but the light for items in display is supplied artificially. Compared with natural light, artificial light is more stable with stronger expressive force. Besides, artificial light is able to effectively control the tempo and color of the whole display space, letting the visual language provide better service for the display.

What's more, perception of the words, background pictures and colors in museums' display space are closely related with brightness. The stronger brightness is, the longer observing distance is.

The observing distance for brightness and colors conform to the following rules: white plus black, yellow plus black, green plus black, white plus green, white plus red, yellow plus red, white plus blue, black plus orange are feebly influenced by brightness, but orange plus black, blue plus black, red plus black, black plus white, blue plus white, red plus white, gray plus white, black plus gray, red plus gray, black plus green, black plus red, yellow plus black are obviously influenced by brightness.

Based on different brightness, figure 2 recommends the right chars and colors.

Strong Brightness		Medium Brightness		Weak Brightness	
Chars	**Background**	**Chars**	**Background**	**Chars**	**Background**
Black	Yellow	Black	Yellow	Orange	Black
Red	White	Orange	Black	White	Black
Orange	Black	Red	White	Black	Yellow
White	Black	White	Black	White	Blue
Yellow	Black	Blue	White	Yellow	Black
White	Blue	White	Blue	Yellow	Red
Black	Gray	White	Red	Red	White
Black	Red	Yellow	Black	Blue	White
Blue	White	Yellow	Red	White	Red
Black	Green	Black	Gray	Black	Gray

Figure 2. Character table for different brightness

Expression ways in museum display and design

4.1 Exhibition plates

Most of the information in museum display is spread through exhibition plates. As a spreading medium, plates are in possession of a great number of pragmatic characteristics such as low cost, convenient installation as well as stability. Therefore, a great many carriers of visual language are made through plates. In museum exhibitions, the selection of plate materials is obviously different from that of temporary expositions. The plate materials used in museum exhibitions mainly include aluminum alloy plate, PVC plate and wooden plate. Plates of different materials differ according to the distinct requirements of exhibitions.

4.2 Light boxes

Application of light boxes are quite common as they mainly count on the brightness of background lights to make the exhibitions are attractive in the public. Light boxes are fixed with some steel bones or model frames with lamp pipes shining behind.

Generally speaking, the information which needs to be illustrated through light boxes is significant part in the entire exhibition. It is sometimes concluded with brief words, pictures or words plus pictures.

Summary

Like human language, visual language is a major medium of mankind's civilization and historic heritage. As the main body displayed in museum space, the role it plays is indispensible and vital. The combination of visual language with museum display means that union of traditional two-dimension design and spatial will be a must in the field of design in the near future.

Based on computer network security in financial informationization construction of colleges and universities

Shizong Wu[1, a]

[1]China West Normal University,Nanchong City,Sichuang Province,China

[a]jccwsz@163.com

Keywords: computer network security,financial,informationization construction,colleges

Abstract: The computer network bring great benefits to the financial information and daily management of university. At the same time, we should pay attention to the potential safety hazard and threats brought by the network finance. We can security network financial information from two aspects of technology and management, technology mainly focus on the configuration and set with the computer application software and hardware; And management is the information security management. According to the situation and conditions of the university itself, considering safety factors, the establishment of a stable security network financial information management system, it is the important foundation of financial management in colleges and universities, is also the important prerequisite for healthy and stable development in colleges and universities.

Introduction

In the information age, widely used in modern computer network technology will become the inevitable developing trend of financial management and accounting,because the financial accounting demand timely, accurate and complete information.But under the network environment of financial management and accounting system in an open platform, it will inevitably face many risks such as hacking, virus infection. Solve the problem of financial network security and data security is the premise to realize network financial management and accounting.

As a new financial management mode,Financial network truly achieve the financial work of mobile, it brings a change of financial management science, develops the network fastly. Network financial security is not only a technical problem, but also the safety management problems, we must considering safety factors according to their own actual situation, setting reasonable goals, technical case and related supporting regulations, etc., to establish a secure network financial system, to bring financial management to a new level.

Financial network security problem of universities.

The inappropriate use of financial software.In colleges and universities, many sort of financial software are used, the software vendors have different technical ability, part of the software in the design when there is a loophole, most likely by criminals or hacker attacks, and even the whole system paralysis, leading to loss of data.At present,The colleges and universities lack of strict financial software on the user privileges division: refer to history of financial information and financial data revision history record is too general, didn't do the strict records of user level, when a financial accident will not work by looking at the history of illness.

A computer virus spread and attack.Computer virus spread fast, financial personnel download network information freely, use mobile hard disk, usb flash drive, and so on and so forth. Combined with some computer did not install a firewall, and even not installed antivirus software or no update virus, can cause computer network virus, not only cause serious damage to the users' personal computer security, but also affect college financial network users. Even may ruined the database, data is damaged, a serious threat to the network information security.Some illegal users through legal user password theft, illegal user identity, into the network to tamper with or damage of the data, the illegal invasion behavior put forward great challenge to college network information security. With the rapid

development of Internet, network attack form is more sophisticated, may make it harder for users to notice. Everywhere on the network of trojans, virus software, such as in Mass under the flexible use of attackers easily achieve the goal of the attack, causing a system crash or run, lead to the database is destroyed, a serious threat to the network information security[1].

Defects in the financial networks configuration.Configuration is incomplete or improper configuration will affect network information flow, even will cause the network paralysis, make the processing of financial data cannot be correct, complete, caused serious data leaks and lost. Reality has the following a few questions. Such as network back door failed to timely plugging, server Administrator account no password or the password is too simple, the database link with SA supreme authority account and provide WEB services account no independent, WEB directory permissions without segmentation, no effective firewall configuration scheme, and so on[2].

There are risks in internal management.In the era of financial network, Some units emphasis on computer hardware and software aspects of risk, ignore the internal staff operational risks, strengthen internal management is important for the financial network.The lack of financial file backup mechanism[3]. At present, the college financial information has become increasingly complex, the information level is higher and higher. In colleges and universities, financial electronic statements inconsistent with corresponding accounting voucher filing. Financial network monitoring and protection mechanism is also weak. Under the Internet environment, electronic symbol is accounting data, magnetic medium is the transmission medium of accounting data and saving way, therefore, under the informationization of financial data, in theory, can be accessed at any time any place. In terms of financial data in colleges and universities, the network protection consciousness is still very weak.Financial personnel in colleges and universities lack of knowledge of computer and network information knowledge, They pay more attention to the normal operation of the financial system than the quality of financial security. In addition, the financial personnel understanding of computer safety management is not clear, understanding of the dangers of the virus and Trojan software insufficiency, the attention is not enough to download the network information, in the department of internal use mobile hard disk, usb flash drive, and so on and so forth. This infection may cause the financial system on the one hand, on the other hand can also cause financial personnel user information being stolen, and financial personnel protection of users' information consciousness is not enough.

College financial network security.

Standardize the use of financial software, improving access to financial software standards. College financial software is different, the software vendors should draw lessons from other institutions and government departments in our country, standardize the accounting software standards, improve financial software of barriers to entry, implemented under the unified financial system architecture universities personality optimization. Lack of specification standard is difficult to effectively upgrade the software, it is difficult to effectively regulate the financial operation process. Colleges and universities can draw on its unique ability of organization, seek common ground while putting aside differences, establish a unified, standard of university financial software. Abroad, can improve the leverage of the financial software provider, regulate the behavior of the software vendors and software quality. Internally, to optimize the financial management, but also helps to improve the financial software upgrade speed, reduce maintenance costs[4].

Upgrade hardware and software , prevent virus attacks.Using hardware firewall. Using hardware firewall through the definition of safety rules, open port and protocol, less as far as possible can effectively improve the protection system of time; The analysis of the firewall log system, reduces the cost of testing safety problems; Graphical interface can effectively reduce the response of the concise countermeasure of the implementation of the time. , therefore, have a hardware firewall system is convenient management system in colleges and universities financial network infrastructure, is indispensable.Install the server version of antivirus software. Install server version of antivirus software is to protect the network security of the other a effective way to improve the protection time, rapid processing of viruses to further improve the responding ability and speed of students.To

strengthen the preventive measures against the virus. First of all, using multi-level multistage other enterprise anti-virus system, the virus to achieve full protection. Second, the firewall technology is adopted to across the border from network information filtering, will visit against illegal intrusion, including virus, in the internal network, thus play a role to protect the internal information.

Strengthen the management of financial network Settings.The configuration directory permissions management. Detailed configuration directory permissions are for the implementation of the access control, user isolation can strengthen the protection ability of the system. Based on the principle of a web site a separate directory, allocation of independent accounts belong to the GUESTS group, don't use the system default account, to web directory, if only run asp, the administrators group is only required to assign all rights; IIS_WPG assigned reading, operation rights; Assignment of anonymous access account read permissions operation.Strengthening the management of database link bank account and computer users. In order to strengthen protection, improve the strength of access control, database link account will not be able to use SA, can separate in the database server to establish an account, follow the principles of a database to limit an account, this account is only available to the general library, read and write access, or even just read permissions. In this way, even if the injection, also can't through the bank account set up system, while SA privileged accounts can be. For other relevant account password must conform to the requirements of the complexity, it is best to common combination of letters, Numbers and symbols. Use the user name password system security technology method, it can be in the boot password, network user name password and application system password used on three levels. A user level, database level control and network system level control system of multilevel access control mechanism. User level can rational division of rights of network users, is now operating authority centralized management, strong chemical system administrators on each mold piece of software operation of unified authorization, guarding against the illegal users gain access; Database level can prevent the unincorporated member of financial data leakage, reigned change and delete; Network system level to prevent accidents due to power outages, communication line fault caused by the electronic accounting files are damaged or missing. The type, the user's identity, the operation of the system operation, system parameters and the state, as well as between real-time monitoring system of sensitive data and records, the necessary permissions, so that you can for a variety of different permissions for user identification.

Strengthen technical safety measures.Using the data encryption technology, the public network transmission of IP packet is encrypted and encapsulation[5], only the specified user or network equipment to decrypt data, so as to realize the confidentiality and integrity of data transmission. Using vulnerability scanning technology, can to local area network (LAN), a WEB site, the host operating system, system services, and firewall security vulnerability scanning system, the system administrator can check out of the running unsafe network services that exist in the network system, and exist in the operating system may lead to a buffer overflow attack or denial of service attack security vulnerabilities, can also check whether there is a firewall system security vulnerabilities and configuration errors. Intrusion detection technology for suspicious intrusion behavior on the network to make policy response, and cut off the invasion of the source, record and timely notify the system administrator, by all means help system administrators to deal with network attacks, enhance the capacity of the system's security administrator, is considered to be boundary firewall after the name of the second gate. It can also detect an open to the public service of illegal access, is the reasonable supplement of firewall. Using authentication technologies[6], including technology, such as identity authentication, information integrity check to prevent illegal users of the financial system of network attack, information theft and tampering, guarantee the authenticity of the data, integrity, confidentiality, and non-repudiation.

Strengthen internal management.Establish a perfect network system of internal control. Perfect internal control system can effectively reduce the risk of moral hazard due to internal personnel, risk of system resources and computer fault caused by the damage. Under the network environment of financial management system should be established to adapt to the network system of internal control system and control system. Should control range from single financial sector into a common control

and computer management departments. Control mode should be organized by pure manual control into control, manual control and process control with the combination of internal control.To establish the necessary management system. Strengthen the awareness of information security, perfect the rules and regulations. Strengthen the network users to the correct understanding of information security, improve found the network information security problem representation and influence of information security behavior of sharpness, and maintenance of the network information security initiative. At the same time, according to the characteristic of the complex network shares, from the system application, network security, data privacy, information security, etc, to establish information security applications technical standards and specifications. The rules and regulations to establish and improve not just, more important is, must strictly abide by, strong execution, supervision, pay equal attention to. More to manage in place at the same time, the power and responsibility clear, clear responsibility, strengthen the consciousness of society and sense of responsibility. In addition, increase capital investment, improve the management expertise, expand the network construction, personnel real construction of a high quality managerial talent team, improve the security, maintenance and emergency response capacity.Build a network security incidents emergency response mechanism[7]. In the enterprise, the network financial information set of emergency measures, can make the enterprise for a rainy day, in an emergency situation, such as major natural disasters, information system for computer virus in paralysis, able to timely and orderly response to deal with the crisis, as soon as possible to restore enterprise daily production and business operation activities, to reduce the losses to a minimum, the enhancement enterprise's competitiveness and vitality. For emergency mechanism set, first of all, should set up the corresponding contingency plans, for the main direction of crisis management and policy, clear responsibilities in effect at the time of the emergency distribution and personnel changes, etc. Second, is the establishment of emergency department, in terms of network financial information, the focus of the emergency mechanism is set, is in the enterprise information system for related emergency software configuration, including important financial information backup, of the viral attack area of the information or system Isolation and treatment etc.Optimization and attaches great importance to the network monitoring and build a perfect defense measures. Due to the limitations of funds, and other hardware conditions, college financial network monitoring closely enough, hard to prevent vicious attacks. By purchasing a commercial software to achieve effective monitoring defense cost is too high, the uniqueness of the university financial information available to set up a "limit non-isolating" within the control combined with external interface mode, colleges and universities to strengthen the internal financial restrictions island - external interface mode. Its characteristic is the main financial information and financial work distribution in far Internet network, and needs to be released via the Internet or transfer financial timing and financial system has been connected to the Internet connection, and update the data load.

Study on Application of Database Synchronization Technology in the CDIO Teaching System based on Android

Haiyan Hu [1, a], Hui Yan [1,b]

[1] Department of Information Engineering,Jilin Business and Technology College,Changchun,China

[a] hhy1979_711@sina.com, [b]yanhui7125@126.com

Keywords: Android;CDIO; Synchronization Management ;Hash Digest Algorithm

Abstract. As a breakthrough in teaching methods, the teaching system for CDIO talents training is extended to the Android mobile phone platform for engineering talents training better. This paper focuses on constructing the teaching system for CDIO talents training on the Android mobile platform, Hash digest algorithm is applied to the synchronization management of Android platform-based CDIO teaching system databases, significantly reduces the data traffic on the wireless network, and greatly enhances the data interaction between the embedded devices and servers. This application also dramatically reduces the number of write operations on the memory stack and improves the performance of the I/O read-write efficiency of the memory stack.

Introduction

In the age of rapidly-developing wireless internet, mobile phones and other mobile devices have become an essential part of people's lives. Under the circumstances, mobile learning develops as a new style of digital learning. This paper put forwards the Android mobile technology combination with the CDIO teaching model to change the traditional, single teaching methods. This combination realizes the deep integration of relevant technologies from the interdisciplinary fields, applies the "anytime and anywhere" information exchange and means of services to teaching to adapt to students' mobile, effective, synchronic, individualized open learning and, thus provides a teaching platform for training comprehensive talents with CDIO qualities. Students can learn from the teaching system through Android mobile phones, store and process such learning records as learning time, self-testing scores and number of questions, and obtain the updated teaching information from the sever.

Construction of the learning system for Android-based CDIO talents training

The presentation layer is the interface where the system interacts with the user through mobile phones, PDA, UMPC and other mobile terminal devices. This layer also provides different interfaces for different identities (learner, teacher and administrator) to login. The user can access WAP platform through the client to browse the resources on the internet. For the mobile learning system, the internet layer mainly includes the internet and the mobile wireless communication network, and mobile phones and PC can access the uniform resources through the server. The business logic layer is used to package the business services of the system, and is responsible for the application requests of the presentation layer. Here it is mainly in charge of the three kinds of users' business service request for the three function modules: student module, teacher module and administrator module.

The architecture of the system is shown in Fig1:

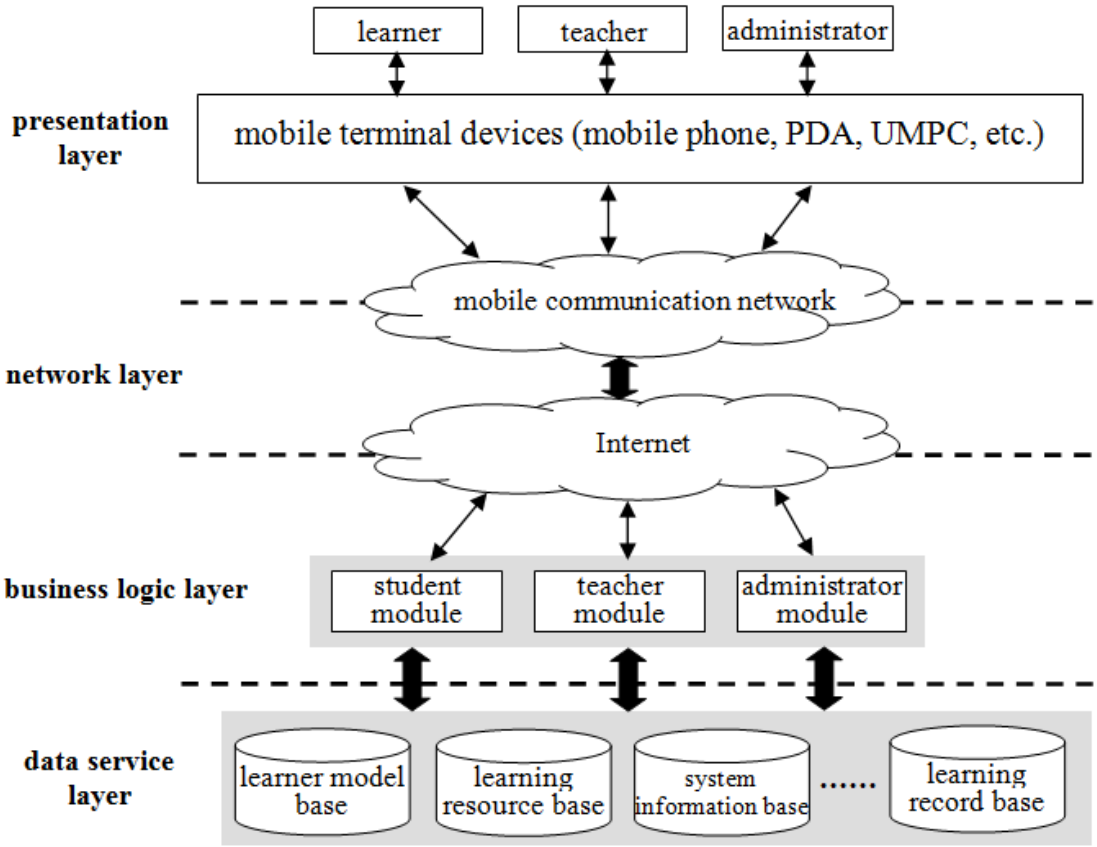

Fig 1. The architecture of the system

Synchronization technology of Hash-based Android system

The process of the synchronization model of Hash-based Android system is described as the Fig.2.The system performs a query operation; the system acquires query information from its local database, and uses Hash algorithm to digest its query data results; the system submits the digest information and query statement to the server database through the wireless network; after receiving the query request, the server database receives a set of data results, and uses the same Hash algorithm to acquire the digital "signature" of this set of data;then the server compares the two signatures; the server only returns the inconsistent data results to the Android system through the wireless network; after receiving those inconsistent data, the system updates its local database and writes them on the memory stack.

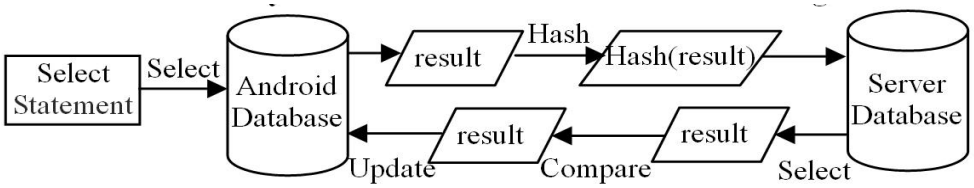

Fig. 2 The process of the synchronization model of hash-based android system

Synchronization of the client database management system in the Android system

After the Select query, N rows of results can be obtained in the storage database of the Android system, which are assumed to be (R1,R2,…,Rn), and the data length of each row is m;N Hash digests are obtained: (H1,H2,…,Hn) ,after Hash algorithm is applied to each row of results, and the length of each Hash digest is n;HE with the length of n is obtained after Hash algorithm is applied to the N rows of results;HL, (H1,H2,…,Hn) and the query statement are sent to the server through the wireless network.

Synchronization of the database management system in the server

The client sends the latest data to the server from time to time to update the data of the server; and it is also responsible for making timely response to the query of the client database service system.

After receiving the request of the client, including HL, (H_1,H_2,…,H_n) and the query statement, the server performs the following operations.It uses the query statement to query the server database, and obtains T rows of data results: (R_1' , R_2' , …,R_n'), and the data length of each row is m;It processes this set of data results with the same Hash digest algorithm, and obtains T rows of results: (H_1' ,H_2' ,…,H_n'), and the length of each digest is r;it applies Hash algorithm to all N rows of results and obtains HE′ with the length of n; it compares HL and HL′ ;if they are the same, according to the features of Hash digest function, it can be certain that the data results received by the client are consistent with the data results received by the server database, and the server database need not return all query results to the client, but informs the client that the data on it are the latest data and the current data on all of its embedded devices are valid.If HL and HL′ are different. The server will compare (H_1,H_2,…,H_n) got from client-side and (R_1' , R_2' , …,R_n') from server-side one by one and all different results will be updated or added. The original data results corresponding to different Hash should all be transmitted back to client-side by network.

The client will update the received different data results to its local database to maintain data consistency with the server.

Experiments show

Given: the system has K records in total, and requires the Hash digest with the length n=32.

It can be computed that the Hash digest results of the two different data have the same collision efficiency: when n=32, K=10000, the collision efficiency equals P. Since the collision efficiency is small enough, the digest can solely represent an original data without conflict. Therefore, this Hash digest algorithm can be used to realize the synchronization of databases. After the use of Hash algorithm, the statistic B of the data volume of the uplink and downlink can be obtained:

The data volume of the uplink:

$$q+n\times(N+1) \tag{1}$$

The data volume of the downlink:

$$(P+N\times z\%)\times m \tag{2}$$

Given: there are 2000 records of query results (N=2000), 10000 records in total. Each original result has 100 bytes (m=100), and the Hash algorithm which produces digests with the fixed length of 32 bytes is applied. There are 200 additional records in the server database (P=200), and the length of the query statement is also 32. There is 10% “dirty” data in the memory stack of the Android system.

The following result can be obtained after these data are substituted into the above formula (1)(2). Comparision of the data volume of the uplink and downlink is shown in Table 1.

Table 1. Comparision of the data volume of the uplink and downlink

Using Hash algorithm or not	The data volume of the uplink	The data volume of the downlink
Without using Hash algorithm	32	100×(2000+200)=220000
Using Hash algorithm	32+32×(2000+1)=64064	(200+2000×10%)×100=40000

It can be seen from the above test that Hash digest algorithm significantly reduces the data traffic on the wireless network and thus greatly improves the data interaction between the Android system and the server.

Conclusions

This paper introduces the CDIO teaching system into the Android mobile platform to meet the requirements of CDIO talents training and make students have individualized learning at “anytime and anywhere”, hence making a breakthrough in the teaching methods. In addition, it applies Hash digest algorithm to the database management of the Android system, which significantly reduces the

data traffic on the wireless network and greatly improves the data interaction between the Android system and the server. This application also sharply reduces the number of write operations on the memory stack and enhances the performance of the I/O read-write efficiency of the memory stack.

Keywords: Ship Handling Simulator; Bridge Resource Management (BRM); Reform of Teaching

Abstract. There is short in the number of large ship handling simulator and it has high failure in BRM training. They could not remain for a long time in the laboratory for teachers qualified with captain and highly educated full-time laboratory personnel. Marine institutions begin to carry out practical teaching reform for these problems, which make people to work hand with policy support and scientific and rational evaluation mechanisms, innovative training teaching methods and establish an objective assessment criteria. By BRM training students enhance the ship's emergency response, role awareness and situational awareness, which have important practical significance to enhance navigational safety and strengthen risk awareness.

Introduction

Bridge Resource Management Course is one of the seamanship professional courses which have been carried out for some time in some institutions. The training purpose is to improve ship management skills on board to ensure the navigation safe, reducing the occurrence of man-made accidents. Entered into force in accordance with the 2012 Manila amendments, most of the crew and students need to undergo mandatory training BRM[1-4]. Therefore, the need to explore new models of a comprehensive experimental practice for ship bridge resource management training based on ship handling simulator to cultivate innovative ability of students.

There Are Some Problems in the BRM Experimental Process

Firstly, it is insufficient number of instruments and equipment which is failure to carry out the experimental of BRM. In order to construct a realistic marine environment and improve practical skills of crew trainees, all maritime colleges and training institutions have developed or introduced large ship handling simulator which is very expensive. BRM training has three of the ship that can accommodate up to 12-15 people at ship handling simulator, however, a maritime training college has only a ship handling simulator, which is in urgent need of 280,000 officers are not trained.

Secondly, ship simulators have different types which are different unstable, such as single-channel fault or visual or radar charts machine crashes and machine image disappears non-normal. Three ships require to see each other at the same time in BRM experiments, one of the ship fails, the other ships will be affected, or even need to exit the system and restart the experiment, the effect of experimental scenarios was greatly reduced.

BRM is a simulation comprehensive experiment at sea about ship bridge resources, which is innovative experiment subjects and higher guidance teacher requirements. Currently, treatment and status of teachers major in marine technology often are neglected, a licensed captain's income far exceeds income in colleges or training institutions. Therefore, it is very great difficult to introduce a practical experience captain at sea as a full-time laboratory assistant. On the other hand, ship handling simulator is a large equipment, it’s operation and maintenance need specialized knowledge of higher laboratory assistant. And higher education faculty reluctant to stay long in the laboratory because of treatment assessment, so personnel mobility is greater.

Comprehensive Experiments Conducted Design and Practice

Integrated design experiment project design. Change the traditional single confirmatory test project based teaching philosophy, conscious design experiments conducted comprehensive project design. In the design process, we can use a variety of methods, for example, in actual operation, the development of several typical operating regions, namely the development of the reference card title. Title card contains experimental time, scoring criteria, specified experimental waters, vessel name and other basic information. The process of navigating the scene is set, a comprehensive experiment is shown in Figure 1.

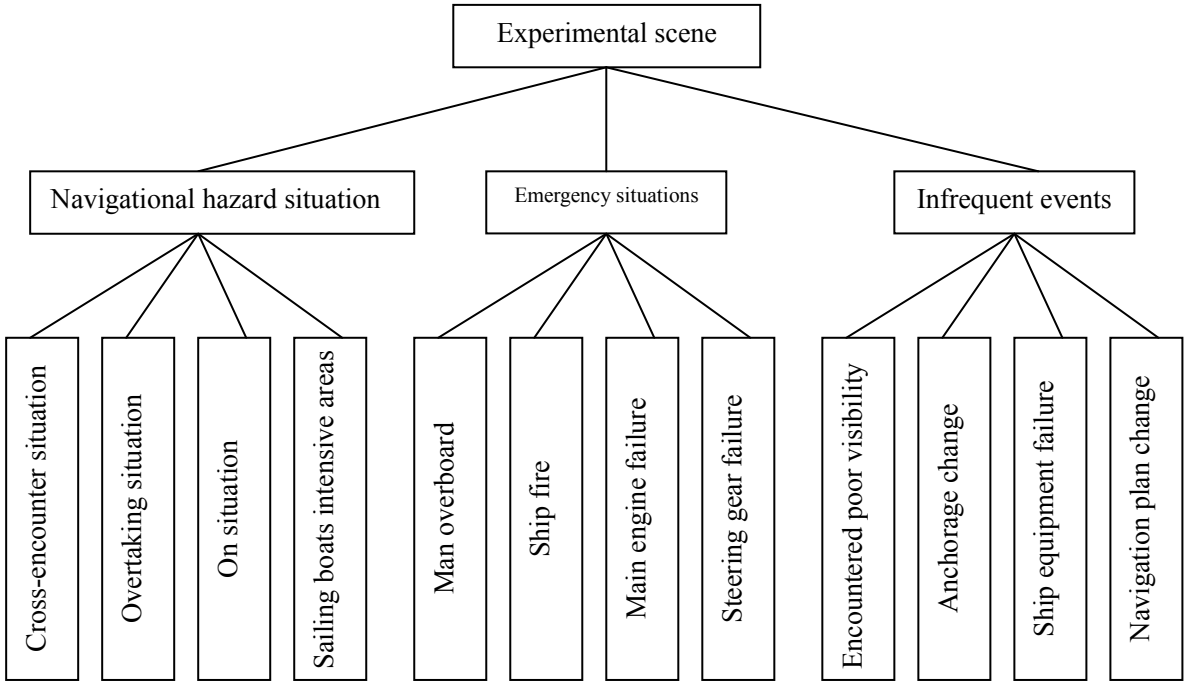

Fig.1. A comprehensive experimental scene

In a comprehensive experiment, we can select one navigational hazard situation, two emergency situation, an infrequent events as the experimental scene for each group.

In the process of integrated design experiment project implementation, the role of transformation experiments make learner's enthusiastic participants increased

A 15-person group, same experiment can be divided into three experimental groups, each group of five people randomly assigned to play the role of each person, who respectively play the role of captain, first mate, two mate, three mate and sailor. After an end of the project in each personnel were summed assume the role of experience. When the next project various roles rotation, so that each different maritime role transformation, participants experiment enthusiasm and enthusiasm, the experimental results are very clear, the role of awareness and situational awareness were trained.

By discussions and interactive teaching, students can think independently and initiative to mobilize the enthusiasm of the experiment. Before the simulator experiments, each voyage plan based on faculty members to develop a given experimental project, team members discussed jointly develop solutions needed to find the voyage sailing books, and emergencies that may arise in practice do good plan. In the experiment, the crucial role of captain, he was commander of the team. When he was in command and the negligence of the details, the team members should remind each other, which was reflecting the sense of team. At this time, the role of guidance teachers was to become auxiliary. The role of each team member responses recorded at the end of the project the collective sum up the discussion. Team experiment can spend 2 hours, one hour to focus discussion. In each group, the captain, first mate, two mate, three mate and sailors take on the role of role are summarized in this group, such as advantages and disadvantages and experiences.

The role of teacher is the key to a comprehensive experimental design successfully implemented. Experimental teaching process and the experimental station instructor trainer's role is also crucial.

In order to ensure the pilot project sporadic and sudden, three teams need constantly to create trouble, such as setting poor visibility suddenly, speed boat as a suspected pirate ship, oil spills, ship fault, man overboard, etc. In order to examine each team 's emergency measures maximize the simulated emergencies at sea. Meanwhile, the two guiding teachers bear the cabin, VTS attendant , ship company roles and timely communication and exchanges with each team. Three ships run at the same time, we must set the order of the items in turn and continue to prevent a failure of the ship and the ship is no other emergency situations occur. In an experiments, we can make the ship's three project settings and communication exchange table. In the 1st of the ship as shown in Table 1, Table 1 is set in the corresponding action on the 1st of each reaction vessel for the cabin, VTS and ship companies have done. If there is no response, the corresponding location in the table count is 0. Recovery column under each action corresponds to 0 means that the ship made the engine room, VTS and the company and the end of the reaction one has counted as a response, no response count is 0. The reaction experiments can record the degree of communication and team communication consciousness. Records from Table 1, the action on the 1st of each boat timely exchange and communication to the company, the key positions with the cabin failed to timely communication and exchange.

Table.1. Set up emergency scenarios and communications records on coach station

Ship 1	Stand by	Poor visibility		Main engine failure		Man overboard		Steering gear failure		Radar Failure	
Set/recovery	Set	Set	Recovery	Set	Recovery	Set	Recovery	Set	Recovery	Set	Recovery
Engine room	1	0	1	1	1	0	0	1	0	0	0
VTS	1	1	1	1	0	1	1	1	1	0	0
Ship company	1	1	1	0	1	1	1	1	1	1	1

Ship 1	Suspected pirates		Compass failure		Anchor		Oil Spill		Others	
Set/recovery	Set	Recovery	Set	Recovery	Set	Recovery	Set	Recovery	Set	Recovery
Engine room	0	1	0	0	1	0	1	1	1	1
VTS	1	1	0	0	1	1	1	0	1	1
Ship company	1	1	1	1	1	1	1	1	1	1

Experimental Evaluation

Its timely assessment to the experiment effects to test the student experiments to form a closed loop of BRM experimental teaching. According to the maritime sector suggested assessment form[5] and the actual situation of the experimental teaching, we make an evaluation criteria and assessment elements which contained in the mission analysis and planning, through the designated waters practical, work attitude and situational awareness. In each elements, simulation experiment accounted for 40%, 60% of experimental evaluation. The overall evaluation have two levels which are qualified and unqualified. Real-time simulation of the case by the transfer of coaches stop playback function, the details of the experiment in the three groups of the ship two hours playback trajectory control assessment criteria, given the objective results. Figure 2 shows that the three cases is the ship track playback experiment teaching after the 1st boat anchor job in progress, the 2nd man overboard boat project has been completed emergency response, emergency steering gear failure being manipulated under the 3rd ship is conduct man overboard emergency operation.

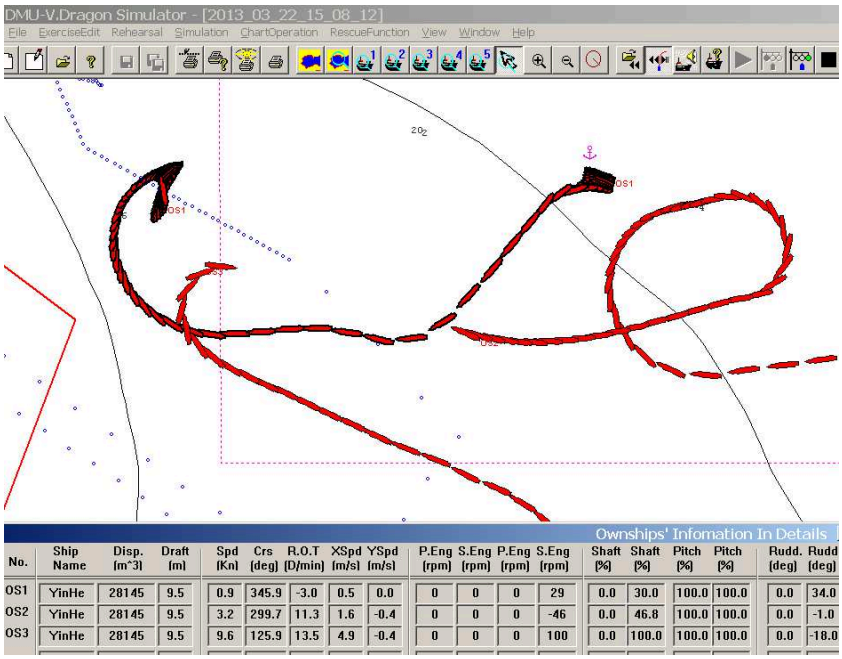

Fig.2. Three ships track playback experiment

Conclusion

In order to make up BRM experimental teaching for few instruments and equipment and high failure rates, we make some effective methods to improve the utilization of experimental teaching equipment. For educated laboratory personnel greater mobility in common, trying to create a bolt from the heart to keep people in a lab environment policy, job evaluation and other aspects. On the experimental teaching methods, by innovative teaching model, the student is able to change the passive learning independent thinking, active learning, interactive learning. Validation experiments to change the traditional teaching based concept, the design of advanced integrated BRM concept design experiments to the complex projects to the environment, can improve their safety awareness and emergency response, in order to minimize the the risk of an accident occurs to a ship .

Keywords: Maintenance Equipment; three-dimensional Information; Synchronous display

Abstract. Based on the current situation that the current ordnance equipment maintenance information management system is not intuitive, a new information system was designed and realized, which could display the two-dimensional Information and three-dimensional information synchronously. This system can well compatible with the existing one. Through studying the analysis of the original data structure, importing way for the 3D model of equipment, synchronous display for the 2D information and 3d model, the 3D information management system was realized, which provides a new digital method for equipment management person.

Introduction

With the development of military information construction, maintenance equipment information management work faces the development of the new challenges, which as the basis for army ordnance equipment finance, storage, supply and management. The original information management system, excel as the main form, can't meet the requirement of information management. Developed with digital visual characteristic of ordnance equipment maintenance information management system becomes real demand.

In this paper, we study the technology of the three-dimensional model combined with 2 d information for the maintenance equipment. Then the digital visual means for maintenance equipment data is realized, which provides correct, complete and intuitive maintenance equipment information for the units at the grass-roots level operators and maintenance persons. The new system can adapt to the ordnance equipment rapid development, realize the general requirements of the ordnance equipment management.

General scheme of the system

A. System Composition

According to the requirements for digital platform, the system can feet needs for different hierarchy and level of equipment management persons. Considering the different users, we explored the system by modular design method. There are three basic function modules, importing and exporting for equipment catalog data module, loading and maintenance for model module, equipment inventory management module. The system can be packaged distributed for different users. The block diagram of the 3D information management system is shown as Fig. 1.

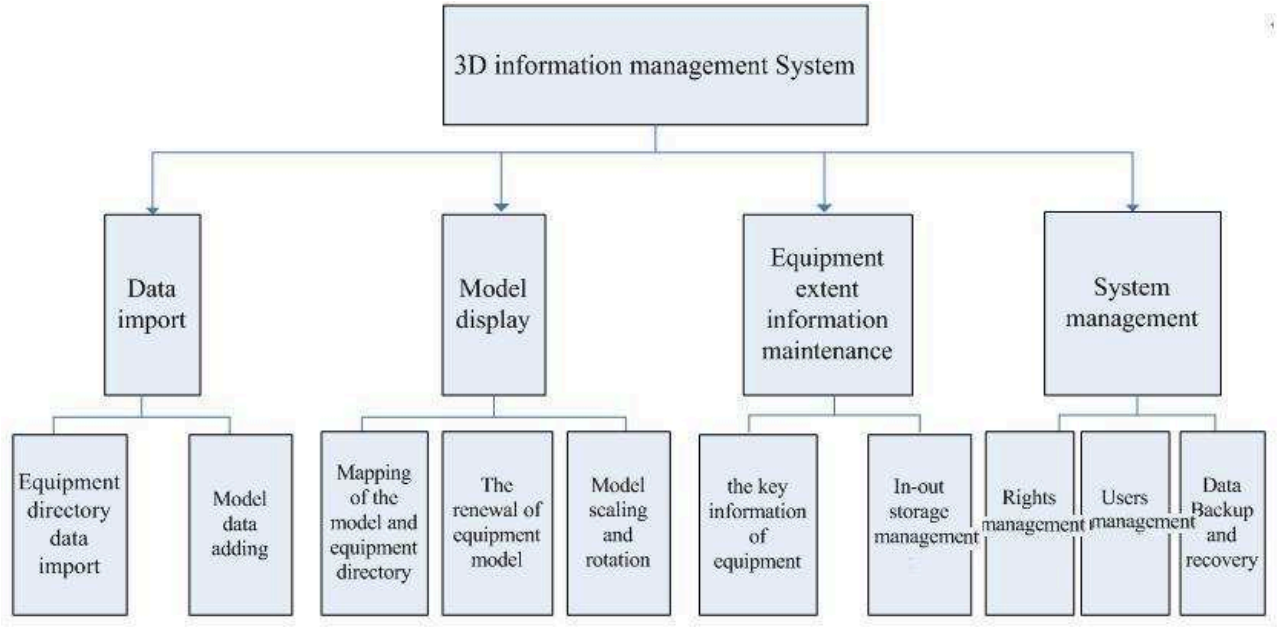

Figure.1 Block Diagram of the 3D information management System

B. Approaches of General Scheme

Visual Studio 2010 is adopt as system integrated development environment in this paper. The maintenance equipment models are built in Solidworks, rendering by the OSG as 3D graphics engine, using access database as data engine. A 3d visual information management platform is provided for user. The diagram of the framework is shown as Fig. 2.

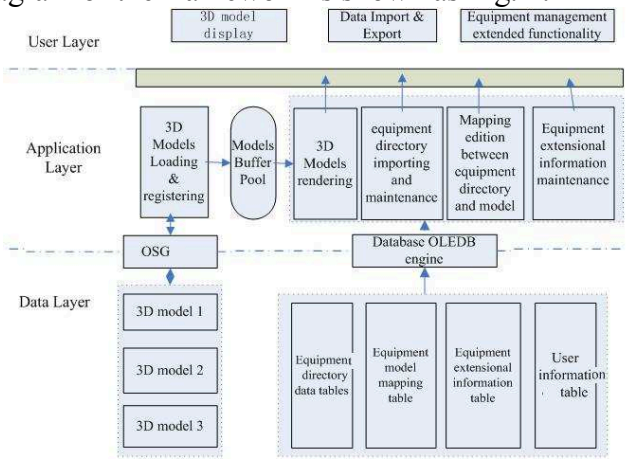

Figure.2 Diagram of the Framework

The Specific Contents of the System Research

A. The construction of digital management platform

Showing the 3D model and its effectiveness is the core content of the digital management platform. Importing the equipment model to the equipment catalog information system, it can provide equipment management persons with intuitive and visual information, can provide the equipment management persons to obtain rapidly the detail information of equipment with short way. For the organic integration of the equipment directory and model data, it need to get the original model data into the appropriate data format, at the same time we need make some new part model of the equipment. The flow chart of building platform is shown as Fig. 3.

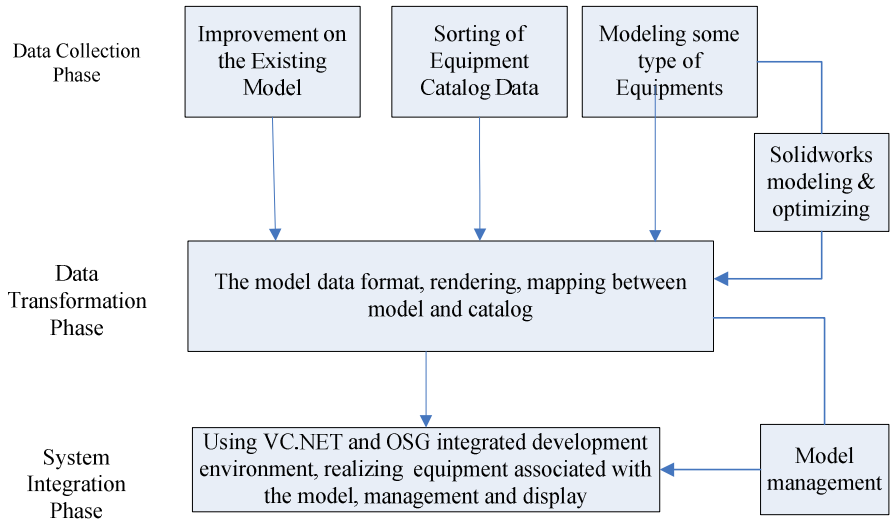

Figure.3 Chart Of building platform

B.Structure Optimization and Data Reorganization for the Existing Equipment Management System Test results

To studying the function, system and the data structure of the existing equipment information management system, it lay the foundation for the new system to compatible with the old one. This new system can be compatible with the equipment data in the old system, can realizing to the existing equipment directory data importing, editing, and exporting.

C. Flexible Query and Association between the Equipment Directory Data and Model Data

Equipment maintenance material catalogs and multi-channel digital visualization query system should be built firstly by systematic and modular design method. According to the equipment code, name, figure number and so on many kinds of ways , the system realize the complex query for equipment catalog data. By setting the part library module, it can realize the general equipment model data query and reuse, and it greatly improve the efficiency on the use of the model data. People can set and edit equipment directory data and model data flexibly, and can realize data query on multi-condition.

D. Equipment 3D Model of Equipment Displaying

By the management platform we can show the 3D model and edit the model attribute easily. The system provides two types of model display function, such as importing the whole model of the equipment and Import folder consisting of many single equipment models. For the first one, the each node of the whole equipment model can be list in the platform, but it doesn't destroy the relationship and structure of mechanical connection in the whole equipment model. It provides the technical foundation for showing the position relationship among equipments.

Key Techniques of the System

A. Equipment directory data import function designing

Firstly the database operation module is designed in order to realize building links with the underlying database. It can recognize the table header of the EXCELL file which user wants to import into the platform. At the same time, it provides the modifying and adding field function.

B. Model import function designing

Import the model file directory is the premise of the model corresponds to the equipment have been imported into the system. The premise condition on importing model is that the corresponding equipment directory has been imported into the system. Importing the model file Performs two ways, which are importing the whole equipment model and importing the model folder. Importing model process is divided into the following three basic process. Firstly, equipment list that has not yet been imported model should be obtained. Then it should traversing all models in folder. Lastly, Finally, the model of file should be copied to the system folder.

C. Model display function designing

This function module mainly aims at synchronous display of the equipment directory and the 3D model. It includes three basic process. Firstly, the specified equipment directory and equipment node should be opened. Secondly, correlation between equipment directory and correspond model should be built. Loading for the first time, the system will automatically build the corresponding relation between model equipment directory according to the of equipment name. The corresponding relationship need to be manually set which system cannot match. The last process is displaying models. The system main interface is shown as Fig. 4.

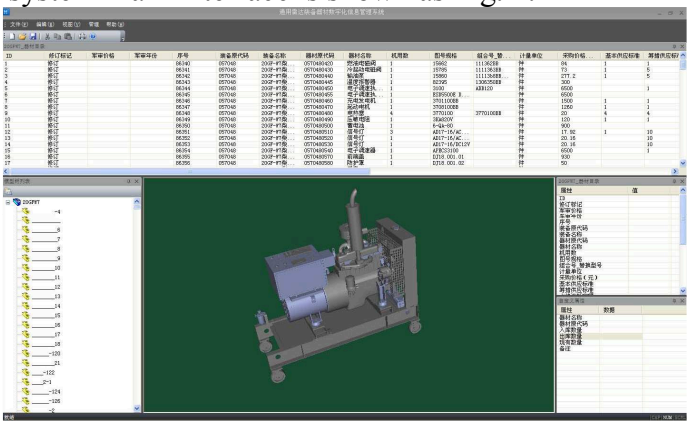

Figure.4 Main interface of system

Summary

By using solidworks, visual studio dot net and OSG graphics engine, we built 3D information management platform of ordnance equipment maintenance in this paper. It well meet the demand of related management persons of the new information demand. It improved the efficiency and level of equipment management informatization. At the same time, as the general platform for the 3D information management of maintenance equipment, this system had portability, expandability, and upgradability. This system could be reference for other weapon equipment management persons or use directly. This platform was of great significance for the management work on the ordnance equipment maintenance equipment informatization.

Study on Fire Safety of Building External Thermal Insulation Materials

Liang Yang

No.2 fuxing road, jinlai road, xiqing District, Tianjin, China

korne@126.com

Keywords: External insulation material, PU, PF, fire performance, heat release

Abstract. Energy-saving and emission-reducing must be achieved based on the reliable performance of fire safety. External thermal insulation material is the main component of external thermal insulation system, and also the main combustion participants when a fire occurs; the combustion performance is an important factor affecting the fire scale of external thermal insulation system. The main material and heat release principle was introduced in this paper, tests were carried out, and fire hazard was analyzed based on large amount of test data. The research will provide theoretical support for external insulation material choice, system construction, fire prevention and rescue.

Introduction

The external insulation system refers to the non load bearing construction built on the building facades, to reduce heat exchange between building and the natural environment. The main component of external thermal insulation is thermal insulation material, other accessories such as, mortar, alkali Mesh, anchor bolts, are all inorganic or metal components, the fire risk is small. although the construction technology will impact on the safety of external thermal insulation system, once fire occurs, which involved in combustion is the huge amount of external thermal material, so the scale of external thermal insulation system fire is mainly depends on the material burning characteristic. So for reducing the fire risk of thermal insulation system, in addition to a reasonable improvement on system structure design and construction process management, reducing the fire risk of external insulation material is also particularly important

Therefore, more information about burning performance and fire risk of external thermal material will do great benefit to improve the external thermal insulation system safety level, optimize structure design, and even improve the fire alarm and fire ability of external thermal insulation system. In this paper, burning performance of external insulation materials were compared, in order to improve the fire performance of external thermal insulation system, guarantee the safety of people's lives and property, and ensure the healthy development of building energy saving in China.

Categories and characteristic of common external insulation material

The basic requirements of thermal insulation material for building includes: thermal conductivity is not more than 0.17W/ (m.K), apparent density should be less than 1000kg/m^3, compressive strength should be greater than 0.3MPa. Thermal insulation material can be divided into three categories according to the material texture； inorganic insulation materials, organic materials and composite insulation material. The main characteristics of common insulation materials comparison is presented in Table 1.

It can be seen from the comparison in the table 1, the inorganic thermal insulation material has significant advantages on fire performance compared with organic insulation materials, but because weather resistance ability and bulk density varies greatly, the application situation and the construction environment are obviously different. Though organic insulation materials have low density, convenient construction requirements generally, fire risk must be considered.

So for the thermal insulation material selection, we should take all of application environment, fire safety, energy efficiency into account, with a full and accurate understanding of the burning performance of various types of thermal insulation materials. In this paper, several representative

thermal insulation material are selected, tests are carried out according GB8624-2012, burning performance is analyzed based on a large number of test data, and further fire safety assessments of external thermal insulation material are given.

Table 1: Main characteristics of common insulation materials comparison

Category	advantages	disadvantages	examples
Inorganic material	High thermal conductivity High compressive strength Easy to Construct	Poor weather resistance Damaging effect on the environment during production process High water absorption rate	Rock wool Foam glass Aerated concrete
Organic insulation material	Low water absorption rate Low thermal conductivity Better compressive strength Easy to construct Steady dimension scale Tolerance in a wide temperature range	Lower usage temperature limit, normally below 80℃ Great heat release Easy to drop when burning Great smoke generation Serious smoke toxicity High price	EPS XPS PIR PUR PF
Composite insulation material	Better insulation performance than inorganic material Good anti condensation performance High compressive strength Strong adhesion	Construction difficulty Long construction period Lower Strength than ordinary EPS	Polystyrene particles Modified polyphenylene

Burning performance of common thermal insulation material

Inorganic material. The representative inorganic foaming material includes foaming cement and foaming glass. The foam cement refers to the light insulation material with a large number of closed stoma foamed by foaming system after intensive mixing of inorganic component and foam agent, the main components of which are silicate. In table 2 noncombustible and combustion heat of the above two kinds of inorganic foaming material are listed.

Table 2 Characteristic of inorganic foaming material

Test sample	Density, kg/m³	Non combustible test			Combustion heat, MJ/kg
		Furnace temperature rise, ℃	Flame time, s	Mass loss, %	
Foaming cement	203.7	2	0	25.3	0.2
Foaming glass	315.6	1	0	19.6	0.0

The inorganic foaming material in table2 have wide application range in thermal insulation field, and fire performance level A1 can be achieved according to GB8624-2012《Classification for burning behavior of building materials and products》. But there are difficulties during construction process because of high bulk density and heavy insulation blocks, so great Bearing weight is required on the building surface. Thermal conductivity of these kind of materials are about 0.06-0.28W/(M.K), so the new energy-saving requirements must be achieved by increasing the thickness of the insulating layer, it will inevitably leads to great thermal insulation material consuming amount . In addition, rock wool products are also be regarded as inorganic thermal insulation material. Rock wool is a kind of Inorganic fiber produced by high speed centrifugal equipment with melting Xuan Wuyan and Dolomite. Rock wool material has the same burning performance with foaming cement. But because of the poor water resistance ability, intensity of Rock

wool will decrease greatly after Water absorption , even fall from the building surface. To improve the water resistance of rock wool products, rock wool is usually be compressed with adhesive added. But the organic adhesive may cause greater heat of combustion, thereby reducing the fire safety.

Organic insulation material. Thermoplastic organic insulation materials. Polystyrene board is a kind of thermoplastic organic insulation materials commonly used in exterior thermal insulation, such material is easy to melt and drop when heated. Polystyrene plate generally includes EPS and XPS, between the two kinds, XPS has the greater strength and higher density. Polystyrene plate is foamed by mixed polystyrene resin and foaming agent while heating at the same time, then continuous obturator structure is formed, so the thermal conductivity of EPS and XPS is very low, usually between 0.02-0.03W/(M.K）.

Table 3 Fire performance of thermoplastic organic insulation materials

Samples	thickness, mm	FIGRA, W/s	THR, MJ	Classification	OI,%

Polystyrene board is very suitable for building external thermal insulation also because of its good mechanical and weather resistance. However, due to its main components are all organic polymers, when fire occurs, polystyrene boards are easy to shrinkage, drop, even burn seriously.

Using polystyrene board as insulation materials usually leads to a fast developing extension on a burning building. The fire continues to spread to the top rapidly, and a empty space can be formed from bottom to the top of the building between the outer protective layer and the main structure surface, making it possible for much fresh air coming into the burning location. Such process promotes the development of combustion process significantly. In addition, rolling polystyrene material droplets along the thermal insulation surface leads to a pool fire on the ground, which also contributed greatly to the fire development.

Thermosetting insulation material

Typical thermosetting insulation material includes polyurethane(PU) and phenol formaldehyde(PF), which will keep their original shape unchanged without any melt droplet on fire. The fire only spread upward on the building surface when such kind insulation materials are applied, generally the lower material will not be ignited, and these also stop the fire to spread to some extent.

Table 4 Fire performance of thermosetting insulation material

samples	Thickness, mm	FIGRA, W/s	THR, MJ	Classification	OI,%
PU 1#	30	$FIGRA_{0.4MJ}$=315.6	5.0	B2(D)	35
PU 2#	40	$FIGRA_{0.4MJ}$ =895.2	4.5	B2(E)	32
PU 3#	50	$FIGRA_{0.4MJ}$=1002.8	6.3	B2(E)	28
PF 1#	30	$FIGRA_{0.4MJ}$ =56.3	3.6	B1(B)	43
PF 2#	50	$FIGRA_{0.4MJ}$ =104.6	4.5	B1(B)	50
PF 3#	50	$FIGRA_{0.4MJ}$ =98.6	5.1	B1(B)	49

PU and PF board has good flame retardant performance, this is because carbonized layer on the burning surface will be formed quickly, preventing the contact between fresh oxygen and the combustible material. On the other hand the carbonized layer also played a role in cooling. But this

does not mean the thermosetting insulating material can certainly obtain high combustion performance level, As we can see from the table, the FIGRA data of PU material is not ideal.This is because, though there is only a short period before carbonized layer on the surface is formed, but the violent burning release lots of heat, so heat release rate(HRR)is very high. While the combustion rate of growth index FIGRA focuses on the heat release rate of growth, so those kind of materials with greater HRR growth rate usually have greater FIGRA, like PU. Also because the carbonized layer only appeared on the outermost surface, Interior materials and back fire surface generally do not participate in combustion, so obvious relationship cannot be found between size and thickness of PU board to FIGRA and THR. But PU is still a kind of thermal insulation material in the construction field, its extremely low thermal conductivity, weather resistance and excellent mechanical properties usually make PU as the main force of external thermal insulation materials field, especially the foam construction capacity which can not be achieved by any other materials, greatly enhance the bonding strength of the insulation base layer and substrate.

On the other hand, GB/T29416-2012《building exterior insulation system of combustion performance test methods》 has been taken into practice in 2013.10, system method was adopted when evaluating the fire performance of exterior thermal insulation system. In fact, the fire risk of PU can be reduced greatly by good external protection and reliable construction process supervision.

Phenol formaldehyde board is another kind of thermosetting material. PF has the similar combustion process as PU, carbonized layer is formed on the sample surface to avoid internal material to contact with flame. Because of better formula composition of PF than PU, most of PF board can reach B1 (B) level, and THR is relatively low. Another advantage of PF is its higher oxygen index. In addition, PF and PU materials burn without any melting droplet, avoiding the formation of flow fire on the building surface and pool fire on ground.

Composite insulation material

Composite insulation material refers to the insulation material interposed between inorganic and organic material. Polystyrene particles are a typical kind of composite insulation material. This kind of material has the advantages of thermal insulation and fire, burning performance A2 can be achieved generally.

However, along with the increasing requirements of building insulation in our country, better insulation performance must be realized by organic materials composited or thickness increasing in polystyrene particles exterior insulation system, these inevitably increase construction difficulty and building load-bearing requirements.

Conclusions

With the development of building energy-saving requirements and industry level, building insulation materials also develop towards the goal of diversification, high efficiency, safety and durability. As the main components of building insulation system, thermal insulation material must play an important role in it. In this paper thermal insulation material is divided into three categories, several kinds of external thermal insulation materials are selected as typical representative of organic, inorganic and composite insulation material, fire performances are introduced and comparatively analyzed. The research of this paper has important significance on research, development and selection of thermal insulation materials and insulation system construction.

Analysis and Control of the Pollution Problem in the Process of Wheat Anther Culture

Yang Xue, Wang Ding, Zhang Li-qin*,Chang Hui-ping, Liu Chun-lei, Han Hong-peng, Xing Wen-hui, Wang Shi-jie

Department of Life Sciences, Henan Institute of Education, Zhengzhou Henan, 450046

Sws211@163.com

Keywords: Wheat anther culture; Pollution; control

Abstract. The prevention and control of pollution is an important technical link in haploid breeding of wheat. From the pollution types,causes and prevention methods in the process of wheat anther culture to analyze how to reduce pollution problems appeared in the tissue culture,so as to achieve the purpose of decreasing the cost of wheat breeding,and improving the efficiency of breeding purposes.

In recent years, plant tissue culture technique (PTCT) has become one of the most extensively used biotechnologies, which is inseparable from agriculture, gardens and medicine etc. wheat anther culture technique is to go on wheat breeding with the PTCT to get the haplobiont, which is very meaningful for shortening wheat breeding time, enlarging breeding scope as well as increasing breeding efficiency. In the cultivating progress of wheat anther, that contamination rate is usually as high as 10%, even to 30%, has become the first problem, which increases the breeding cost, influencing breeding efficiency.

1 Types of contamination

Contamination is the phenomenon of abnormal growth and development of culture material because of microorganism breeding on the culture medium or culture material, such as bacteria and fungus. Common contamination etiologies included bacteria and fungus. Therefore, the contaminations in breeding progress can be divided into two types: bacterial contamination and bacterium contamination. Surface bacteria contamination will show after 1~2 days. Surface of the culture medium will show mucus shape dental plaques. But contamination caused by endophytic bacteria is not obvious at beginning. With the increase of times of culture connection, the quantities of bacteria accumulate, and the contamination occurred [1]. Fungus contamination usually occurred 3 days later, the manifestation of which is the appearance of villiform hypha at beginning then turned to colorful spore layers.

2 Reason analysis (way) of contamination

Reasons of contamination in wheat breeding progress are various, which are as follows: improper explant or halfway disinfect; halfway sterilization on culture media or appliances; nonstandard operation when inoculating; unclean environment of inoculation and culture; break of culture container.

2.1 Explant

2.1.1 Drawing materials

The season and the time of drawing explant influenced the contamination rate of culture material. Generally, spring material has fewer bacteria than summer and winter ones. Material survival rate is relatively high in spring. Materials of wheat anther culture are drawn in mid-end of April and first 10 days of May. Sunny days should be selected and rainy days and severe lowery days should be avoided. Keep in mind that material with water is undesirable. Dew in the morning and rainwater will increase the amount of bacteria in culture material. Then the bacteria will contaminate wheat anther along the water. There will be great trouble to deal with the material. Contamination rate will improve invisibly.

2.1.2 Treatment

The treatments of explant include pretreatment and disinfection.

Wheat material taken from growing field should be packed by plastic wrap and be pretreated for 3~7 days. There are 3 advantages. Firstly, preserve moisture of the material; secondly, be isolated with the outside; thirdly, passivate the bacteria with low temperature. The pretreatment of the material will decrease the contamination rate.

Halfway disinfection of explant is one of the main reasons of contamination. For wheat anther culture, inoculate material is anther, which is very tender, so disinfection progress should be undertaken on the wheatear. Therefore, the selected disinfector should not only has good disinfectant effect to kill all microorganism of the material surface but also do little harm on organization of the material without affecting its growth. Generally, liquor with 75% alcohol and 0.1%mercuric chloride was used as disinfector. In addition, sodium hypochlorite, calcium hypochlorite, bleaching powder, hydrogen peroxide and silver nitrate can also be used as disinfectors. The types of disinfector and the disinfection time depend on the tender degree, the amount of bacteria of the material, which will be decided by the experience of the handlers. Because the alcohol has stronger penetrating power, 75% alcohol is commonly used as disinfection in the progress of wheat anther culture. 20~30 seconds will be OK for disinfection. If the disinfector isn't strong enough, 0.1% mercuric chloride liquor can be used. Because it is hard to wipe off and very harmful to plants, the disinfect time shouldn't be long.

2.2 Culture medium and various appliance

Culture medium and all appliance used in the inoculation process should be disinfected strictly. Halfway disinfection will lead to high contamination rate.

Autoclaving is usually used to contaminate bacteria on culture media. With autoclaving, contamination should be lasted for about 20 minutes, so as to get better contamination results. Be attention that the cover of the autoclaving pot should be tight to get better sealing condition, or contamination temperature can't meet the demand, which leads to halfway contamination on the culture media. Besides, the components, which can't be contaminated with autoclaving method on the medium, such as some certain hormone, should be contaminated with bacteria proof filter. Then add them to the culture medium on the super-clean bench. The contaminated medium should be preincubate for 3 days. If the contamination isn't thorough, the microorganisms will occur during preincubation.

Generally, before the entry to the vaccination room, all kinds of appliances used in the vaccination progress should be autoclaved. Without thorough contamination of these appliances, contamination rate will be very high. Culture dishes and ironware should be packed with multilayer paper when going on autoclaving. Make sure the integrity of papers to avoid secondary pollution when touching air.

2.3 Inoculations

A lot of material and goods will be used in inoculation link. Labile factors of environment and human increase the possibility of microbial contamination on the culture medium. Only every step was treated strictly in the inoculation progress that the contamination rate would be lowest.

2.3.1 Disinfection of the inoculation room

Fungus exist in the air of inoculation room, so regular disinfection is needed. In common, mixture steam of formaldehyde and potassium permanganate (or 70% ethyl alcohol and 0.5% phenol) is used to disinfect [2]. Research of Yiting Wang [3] shows that formaldehyde fumigation can decrease the fungus by 87%~100%, and regular disinfection restrain bacteria in the culture environment effectively. Before inoculation, the room should be contaminated by ultraviolet ray for 20 minutes to decrease the amount of bacteria.

The ground should be often swept with disinfectant. Except conventional clean, before and after inoculation the ground should be swept once to make sure the low content of microorganism.

2.3.2 Use of super-clean bench

Classify and identification of tissue cultured seedling contaminant did by Zhou Junhui [4] showed that most microorganism came from air of inoculation room and exhaust of super-clean bench air blower. Proper usage of super-clean bench is helpful to lower the contamination rate of wheat anther culture. Before inoculation, the super-clean bench should be ventilated for 30minutes firstly. Then the board should be disinfected for 15minutes with UV lamp. Before operation, the operator need to sweep the board with 75% alcohol wipes to kill the bacteria and fungus.

2.3.3 Human factor (inoculation process specification)

In the inoculation progress, irregular operation of people is one of the main reasons of contamination, especially fungous contamination. To reduce the contamination rate, standard operation is necessary in the inoculation progress. The follows need to pay attention to.

(1) Hygiene of operators. Before the entrance of inoculation, operators should wash their hands carefully, especially the nails. In buffer room, they should change their cloth to lab-gowns, slippers, lab-caps and respirators. Besides, their hands and arms should be scrubbed with 75% alcohol wipes as well as the ectotheca of the culture bottle.

(2) The use of metal utensils especially tweezers should be standard. The anther was inoculated on culture medium in the process of wheat anther culture. Anther need to be taken out by tweezers from the florets, and then put them on the medium. In the process of taking anther, glumes should be wiped off firstly, then use a disinfected tweezers to take the anther. Tweezers can't be mixed. So operators should contaminate the tweezers in time.

(3) Avoiding petty action. In preliminary stage, operators aren't familiar with the operation procedure. Some petty actions occurred, such as play their phones or touch other place. If return to the super-clean bench without disinfection, materials on the bench will be contaminated. Therefore, for beginner the contamination rate is relatively high, even to 100%.

(4) The anther from the touched material by hands can't be used.

(5) On the premise of standardized operation, inoculation speed should be as fast as possible. the less the time, the lower the contamination rate.

2.4 The management of the culture room

Unclean environment or culture container damage will increase the contamination rate. So pay attention to the management of culture room constantly. Specially-assigned person is necessary to manage the culture room.

Wheat anther culture should go on in specific culture room. Air and the ground will breed bacteria if the culture room was free for a long time. Therefore, before using the room should be disinfected with mixture steam of formaldehyde and potassium permanganate. As for busy room, it is necessary to be disinfected constantly with mixture steam or 75% alcohol mist spray. The culture room should adjust temperature and humidity a few days earlier because wheat anther culture needs proper condition. In mid-end of April, indoor temperature is about 15~20℃. it can't meet the requirement of anther inoculation on the differential medium. So the culture room should rise the temperature 1~3 days earlier as well as the humidity.

In the culture process, ultraviolet sterilization for 10~15 minutes is needed. And sweeping the floor with disinfectant is also necessary to keep the environment clean. Observe the growth of culture material and take note carefully. Contaminated culture bottle should be isolated in time. Besides, culture containers may be broken or the sealing material may be loose. If these phenomenon haven't been found on time, culture material may be contaminated.

3 Prevention, government and control of contamination

3.1 Prevention and control of contamination

Reasons of contamination have been discussed above. So we can take some specific measures to prevent contamination.

(1) Draw materials at 9~10 o'clock AM and 3~4 o'clock FM of sunny day to avoid rain, haze, smog and dew.

(2) Do better pretreatment, and contaminate explant thoroughly.

(3) Contaminate culture media and appliances used in inoculation process thoroughly.

(4) Do standard operation in inoculation link, follow the Aseptic operating procedures strictly.

(5) Better management of inoculation rooms and culture rooms, and keep them clean.

(6) Observe the culture material carefully to find and change the broken culture containers in time.

3.2 Government and control of contamination

As for the government of contaminated tissue seeding, antibiotic was widely used. But is has bad stability. Classify and density depend on the experiment data. So in the culture of wheat anther, antibiotic is not used. In order to prevent cross contamination, the whole contaminated bottles with material should be disinfected with autoclaving, then to wash them.

The Research of Wisdom Campus Construction and Development Based on Internet of Things

Wang Yipeng

Shandong College of Tourism & Hospitality, 250200

embird@126.com

Keywords: Internet of things, wisdom campus, construction development, student teachers

Abstract. With the continuous development of science and technology, new information technologies such as Internet of Things, Mobile Internet quickly get into various industries. The vast majority of colleges and universities are actively constructing wisdom campus based on Internet of Things to effectively integrate campus personnel identification, library management, campus id and other information, and to ensure digital resources integration and sharing. This article mainly aims at further exploration of the construction and development of wisdom campus based on the characteristics of Internet of Things.

The Internet of Things and wisdom campus

A. The concept of Internet of Things

The Internet of Things is physical Internet which can achieve global objects'real-time share information. It takes Internet, RFID technology, and EPC coding technology as foundation, and makes use of computer Internet to share information. The Internet of Things is very common in our life, which only need to embed one transceiver of middle or short distances in all kinds of daily necessities, and can provide people with a new communication dimension in communication and information world, and expand traditional human communication interconnection of any place, any time, any people to the category of physical interconnection, and the interconnection of things and people.

The Internet of Things system is structured, including comprehensive perception layer, reliable transmission, and intelligent processing layer. Comprehensive perception layer makes use of various means of perception, acquires real-time object dynamic information, such as two dimensional code, sensors, blue-tooth devices, which can get real time information of objects, and they can get instant recognition like sensory organs, and gather data information. Reliable delivery layer can use all sorts of information networks, Internet perception information in a timely, real-time, accurate and reliable manner. Intelligent processing layer can analyze and handle huge amounts of information data, control object through intelligent technology, and help make right decisions, and connect people and things.

B. Wisdom campus concept

Internet of Things technology helps people obtain, transmit, and use intelligent information. It gradually promotes the construction and development of wisdom campus at the same time of changing people's life, work, and study. The acceleration development of Internet technology achieves highly sharing of digital campus internal resources, and information flow, internal teaching environment, education resources and teaching activities are gradually tends to be digital. Wisdom campus has three distinctive features: first, wisdom campus can provide comprehensive and systematic intelligent perception teaching environment for teachers and students and a comprehensive information service platform, promote the roles'personality development of teachers and students; Second, wisdom campus can fuse information service on the basis of computer network technology into various application service areas, and ensure the interactive collaboration of resources mutual connection and related personnel in the university; Third, wisdom campus can use intelligent sense environment and comprehensive information service platform to let the school be connected with the outside world, and perceive each other.

C. Wisdom campus based on the Internet of Things

Wisdom campus is on the basis of digitalization, which takes data information network as the connection, and use digital networking of things technology to comprehensively manage campus environment, resources and activities. Wisdom campus based on Internet of Things can not only provide a more convenient, efficient, and intelligent campus environment for teachers and students, it can also integrate the currently most fashionable popular intelligent transportation systems, energy conservation and emissions reduction system, security monitoring systems, and mobile application system into wisdom campus construction, and get it into education informationized, scientific decision-making, management standardized high quality teaching environment, and improve the quality of teaching. The details are as follows:

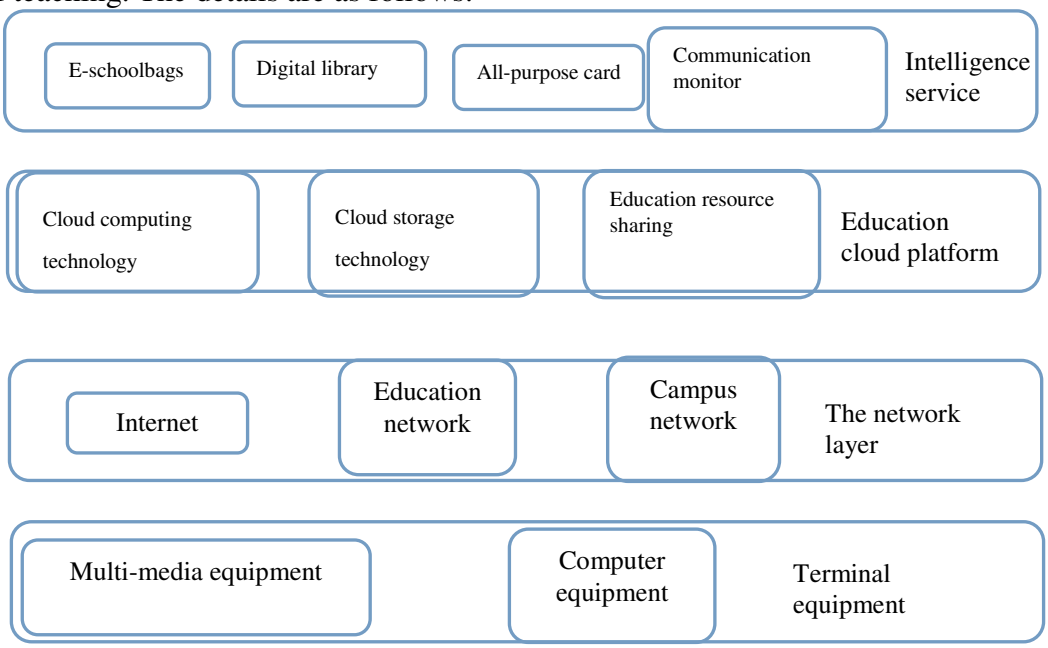

Figure 1 Wisdom campus structure based on Internet of Things

Effective Measures of Wisdom Campus Construction Based on The Internet of Things

Effective construction of wisdom campus based on Internet of Things should be on the premise of campus network, and at the same time take teaching resources as the core, and establish a management platform with fused information to ensure that campus internal becomes digital and intelligent integrated management network platform.

A. Build a unified teaching platform

Wisdom campus should actively build a unified teaching platform, vigorously introduce domestic and foreign high-quality digital teaching resources, give all kinds of high quality network courses at the same time, establish a comprehensive network teaching cloud database; At the same time, also construct digital library and virtual laboratory and truly unify teaching resources ‘flexible open of public service platform.

Network teaching platform and teaching database are important platforms to ensure school education informationization, which can realize the integrated management of teaching resources, effective help teacher prepare lessons, online teaching, students training, really carry out students' autonomous learning, provide a good chance of communication for teachers and students, and co-construct and share teaching resources. School administrators can understand teachers and students ‘teaching status and evaluate teaching quality through unified teaching platform in a timely manner; Parents can understand students' learning in school through this platform; while companies can help guide students practice teaching through the platform. In short, the establishment of unified content couplet teaching platform not only can promote scientific utilization of teaching resources, bring more high quality resources sharing service for teachers and students, also can improve the students' learning quality, enrich students' knowledge, and strengthen students' various skills.

In addition, colleges and universities should actively build cloud computing service platform. Through the establishment of teaching cloud database, develop network teaching course, including continuous integration of the existing teaching resources to achieve the sharing and application of teaching resources. And cloud computing service platform can integrate large purchase high quality resources to eliminate the limitation of heterogeneous systems, avoid internal barriers of resource sharing technology, improve the whole service level of library, effectively display teaching resources, and provide teaching resources to the users through the directory joint, retrieval unification, document delivery, and other functions.

B. Construct unified data platform

Due to long-term lack of unified and effective planning and leadership department of traditional colleges and universities information construction, colleges and universities departments form independent college information application system and information isolated island, and gradually form stable data repository, but resources data are unable to achieve full sharing between subsystems, which is no good to the uniform data query in colleges and universities, and data applications.

Wisdom campus basic task based on the Internet of Things is to make full use of the campus existing application system and information data to construct a unified data reception. And the key of wisdom campus construction is to establish a unified platform for data fusion, accomplish campus data resources integration and sharing of information management, and provide users with high-quality service data fusion. Wisdom campus data come from other entities related to learning teaching in addition to information relating data from school business administration. Due to different entities have different heterogeneous data sources and management mechanism, the lack of unified platform data sharing will not provide good data fusion for campus user services. To sum up, only when university actively build unified perfect data integration platform, can the construction of wisdom campus based on Internet of Things be built smoothly.

C. Construct unified information publishing platform

The unity of wisdom campus development information publishing platform can provide users with efficient and fast information terminal content management. When the content play, style management, material management, task distribution of each terminal are through campus center control point, they can get unified management, comprehensive distribution, and comprehensive monitoring by all terminal equipment's.

D. Construct unified identity authentication platform

Building a unified identity authentication platform is an important content of contemporary new wisdom campus construction. Unified identity authentication platform not only can provide the user with a centralized user authentication management and business integration environment, also can solve many problems of the traditional college certification model such as too complicated to use, slow, poor portability and safety concerns. It provides comprehensive unified user identity authentication service to wisdom campus every application systems, and can also manage the users'digital identity information in information system. As a result, the user simply needs a user name and password belonging to him to use the entire application system authorized by wisdom campus, which effectively avoids repeated logging bad situation. And, in wisdom campus, some important documents and goods are to be labeled qr code and GPS, perception and track function effectively, guarantee the safety management of items, positioning monitor vehicles entering the campus, and ensure traffic safety campus order. In some special area of the campus, set intelligent sensor to implement safety monitoring. Once suspicious, perception will alert management center and begin in-depth analysis of events.

Wisdom Campus Outlook Based on Internet of Things

A. Efficient visualization intelligent management

Wisdom campus based on the Internet of Things can directly connect each physical object in campus environment, at the same time, perceive campus information, gain comprehensive and collated campus latest data information, and do data processing analysis, find out problems and put forward relevant basis for managers to solve the problem. This wisdom campus visualization

environment on the one hand can provide efficient service for campus management, on the other hand it can also implement campus humane, scientific and intelligent management, and control real time campus object data and feedback information in time.

In the wisdom campus environment based on the Internet of Things, teachers and students can not only conveniently complete the identity recognition and attendance record, also can visually monitor campus environment and security system, connect each network, and control intelligent network through variously installed perception of human body movement, sound, temperature, light sensors on the campus, effectively implement the wisdom management of internal campus teaching environment, and safety environment.

B. Build teaching environment of wisdom

The development of network technology provides a more convenient way for people to get a lot of teaching resources and learning materials, but the network's virtual learning environment is always lack of authenticity and touch, still cannot restore the real scene of teaching experiment. Internet technology can effectively connect the real world objects, fully integrate real learning space and virtual learning environment, and achieve the good purpose of physical space and digital information space interconnection. Above all, the Internet of Things can realize the digitalization, visualization and networking of each object on wisdom campus. The teachers and students can have real perception teaching scenario, operate and learn the laboratory research object of experimental equipment, experimental site, also have close observation of experiment, effectively promote human-machine interconnected, entry interaction, and provide more opportunities to communication between teachers and students. In addition, the Internet of Things can also integrate the existing campus teaching platform. Students complete the learning activities by remote control experimental equipment, which provides more broad space for development and quality management services for remote teaching activities. Internet of Things, therefore, provides strong support for teaching activities in wisdom campus, eliminates sharing obstacles in teaching equipment, breaks the limitations of traditional teaching, strengthens students' practical operation ability and inspires the ability of thinking.

C. Implementation of regional resource sharing

To realize fair education, effective means are used to solve major issues of co-construction and sharing of education resources in education career area. At present, the colleges and universities deepen reforms, and gradually implement key school system, which results in a certain gap among different schools in the area. This is mainly embodied in the difference high quality education resources of colleges and universities. Colleges and universities use the Internet of Things technology to make the resource equilibrium among institutions of education. Such as some large high quality laboratory equipment, library resources can be shared to achieve the co-construction and sharing of regional colleges and universities teaching resources through the Internet of Things technology. The teachers and students of different areas can have the same and equal education resources to achieve "low cost, high quality service". On the other hand, students can also choose the appropriate content according to their own hobby, meet the demand of their own learning, improve the liquidity of learning information, deepen students' understanding of knowledge and understanding, and help learners establish collaborative innovation partnership. Wisdom campus based on the Internet of Things, therefore, has a good development potential. It can effectively improve the level of teachers' level of colleges and universities, eliminate the difference of regional colleges and universities teaching resources, and improve the utilization of teaching resources.

D. Broaden learning space

The Internet of Things technology has extended learning space, provides development potential of service, which can help students combine the theoretical knowledge and teaching examples they learned in class, eliminate the problem of theory breakaway from teaching practice. And, Internet technology connects college education resources and related closely with the company, the enterprise resource effectively, which truly achieves the bidirectional interaction between campuses and enterprises. Only by establishing a good strategic partnership with complementary advantages between enterprises and companies, on the premise of improving teaching quality, can students'

innovation ability and practice ability be strengthened. Besides, university education management mode can extend through the Internet to all areas, and implement intelligence service of multidisciplinary and cross area, truly meet the needs of mobile learning, and provide users with ubiquitous resource management services.

Conclusion

To sum up, the emergence of the Internet of Things effectively promotes the development of college education informatization process, brings more innovative services and innovative applications for colleges and universities education, which greatly promotes the transformation of traditional teaching mode, and management mode. Wisdom campus construction based on Internet of Things not only gradually optimizes the environment of teaching, but is an important way to deepen teaching reform, and an important direction of future education. Wisdom campus construction based on Internet of Things aims to effectively implement teaching wisdom, management wisdom and scientific wisdom, wisdom of life and service, and to make teachers gradually update teaching ideas, innovative teaching mode, and provide more high quality teaching service and technical support for students.

Abstract. Emergency plan is crucial to efficient fire recuse. Facing with the existing problem of China's fire fighting and fire emergency plans' status, this article firstly describes the progress in emergency plan and a variety of emerging Internet of Things technologies in fire rescue, then proposes a new form of fire rescue emergency plan which integrates the techniques of Internet of things, VR (virtual reality) animation, GIS and indoor positioning technology. The integration is an innovative way to enhance fire supervision, to improve fire-fighting and rescue capabilities, and to achieve the fire management efficiently, powerfully and more intelligently.

1 Introduction

With urban development, the buildings are built much higher and their area is getting much larger, also more and more staff -intensive. Also a variety of underground space, as the underground street, underground shopping malls, underground parking, underground buildings, etc. link together , as if they form into a small underground city. This particular space is crowded, narrow export, beneath the ground, rapid and effective rescue is very difficult. Once emergency occurs, whether from internal or external, it's very difficult to implement the rescue [1].

When Meng Jianzhu reported the work on Fire Rescue to Chinese State Council, he summarized the main issues in current firefighting: fire safety infrastructure suited to the economic and social development situation has not fundamentally changed ,fire rescue and security capability not meets the social needs situation has not fundamentally changed, public fire safety awareness not suites the social requirement situation has not fundamentally changed ,so we are still in the fire-prone, fire-much period. About the next step , Meng Jianzhu proposed "it needs to further enhance fire professional team construction and to build a sound fire emergency rescue command platform and social linkage mechanism, to improve rescue emergency plan , to strengthen the special fire-fighting and tactical research and professional training, and to enhance the combat effectiveness of the fire emergency rescue".

2 Progress on fire emergency plan

There are two kinds of fire emergency plans. One is paper-based, and the other is digital emergency plan.

(1) Paper-based emergency plan

The fire police prepares a paper fire emergency plan for each fire safety key unit, and divides plans into level-one, level-two, level-three and several cases of different fire area. On one hand, the capacity of this plan is large, and storage is difficult due to the fire units' quantity; on the other hand, when a unit is on fire, it is difficult to find the suit plan from a large paper emergency plan. Emergency plans still have some other problems, like complexity of preparation, difficulty of deduction and amendment, low utilization, poor practical applicability.

(2) Digital emergency plan

The research of digital plan technology is emerging in recent years, it has gone through several stages as follows from concept proposed to now:

The first stage: the electronization of fire emergency plan. Built on the basis of the information management system, some functions have been achieved: emergency plans text editing, classification search, add, delete, as well as the organization and management of the sub-text. However, the digital plan is simply digitized store in text, only providing a number of conveniences on the information finding.

The second stage: the visualization of fire emergency plan. It is built on a comprehensive digital software platform, and has functions of risk analysis, comprehensive judgments, decision support, can automatically generates digital plans. Therefore, it can be used to address the problem of less information, accessing to information inconvenient and not intuitive. It can combine the graphic, text, audio, video and other elements to achieve the plan execution process visualization. The emergency plan has some features that strong visibility, high maneuverability, intuitive information. Meanwhile, it can also be used in portable and flexible command system, such as laptops, PDAs and other forms of portable equipment [2,3] .FIS (Fire Information System) based on GIS by Zhang Juanxia makes full use of confined manpower and material resources to finish the fire control tasks efficiently [4]. The Fig. 1 below shows its functional framework.

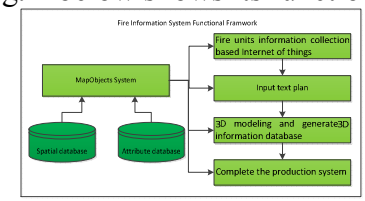

Fig. 1 FIS functional framework

FIS can achieve the management of 119 receiving and responding to the alarm, fire information protection, fire emergency plan making, data maintaining and the disaster prediction. It can efficiently solve the problems of fire control by using all kinds of data from Internet of Things.

Afterwards, researches about emergency plan based on Internet of Things developed rapidly in the field of firefighting. Beijing has established Internet of Things fire-fighting monitoring system and realized the visualization and automation of data thoroughly. The Fig. 2 below shows the Internet of Things constitution about the firefighting.

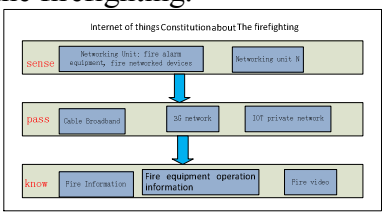

Fig. 2 Internet of Things constitution about the firefighting

By using the detection results of video surveillance and all kinds of sensor such as smoke detector, light detector and temperature detector, also the new technology arranging server and managing data like cloud computing and cloud storage on cloud infrastructure, it can achieve receiving the alarm, transporting the video, collecting the vehicles' running state, automatically monitoring online, searching and counting, publishing the information etc.

The third stage: the intelligentization of the emergency plan. Recently, most of the emergency plans display in paper forms or 2D electronic forms, which have less information than 3D and needs firemen know well of the fire places. Through the 3D way can we make swift and right decision to find out the road, water source, distribution of buildings and escape routes in the rescue scene [5].

Using the advanced computer technology, CONECT, VR(have advantages of making interactive virtual environment and reappearing the real city) technology to research 3D GIS is applied to the fire-fighting and fire drill .It provides the fire forces an easy-operating and intuitive interface of 3D digital fire emergency plan and vivid training course, boosting the Fire Station's rescue ability greatly. Therefore, we utilize the new technology to train, assess, and develop firemen to formulate sound emergency plan.

3 Current problems in fire emergency plan

The limitations of digital emergency plans influence its large-scale promotion and application. It mainly shows in the following aspects [3]:

(1) High production costs. Digital plans are usually made by digital multimedia technology, which is strong technical that non-professionals generally find it difficult to make independence, and expensive that usually cost thousands or ten thousands RMB.

(2) Long production cycle. Digital fire emergency plans need to have text, live pictures, various deployment diagrams of different stages, power calculation ability, and even 3D figures, a key unit's emergency plan usually takes at least two weeks or a month.

(3) Difficult to make. Due to technical reasons, the digital fire emergency plan requires several types of 3D software, graphics, programming, it is difficult for the basic staff to make. Making this kind of emergency plan is only products of a few patents or software companies.

4 Future trends and prospects for Fire emergency plan

The emerging network technology provides an important way to solve the contradiction between the present situation of fire management and the application requirements. Supposing to combine GIS and future indoor positioning technologies, then it can provide strong technical support for the innovation of fire supervision and management, also the rapid and effective fire rescue; additional adding the Internet of things ,then we can build an intelligent 3D fire emergency plan based on remote monitoring system. For some sites, particularly crowded places where it's vulnerable to fires, explosive agencies, higher buildings, and other fire risk agencies, we can monitor fire facilities' running status, unblocked fire exits, and the fire control room, also combine the fire events with real-time video to achieve remote real-time monitoring. Also using VR animation to dynamically simulate the fire occurrence and development of fire agencies, allowing firefighters immersive experience the building environment of the agencies, to be familiar with fire-prone places and know how to act correctly; while achieving Fire training and assessment . Adding 3D structures of the building's external environment and indoor electronic map, can achieve the finding and positioning of outdoor fire vehicles, fire water, etc... Indoor positioning technology can locate the people trapped in fire, thus shortening the rescue time and help solve the search and rescue difficulty. Comprehensive analysis, we can establish 3D fire rescue system based on the above technologies, it should have features showed in Fig. 3:

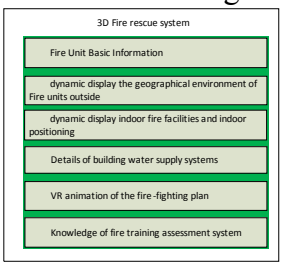

Fig. 3 3D Fire rescue system

The 3D emergency plan based on the system has some features: strong visibility (widely monitoring system), high reliability (truly present the building structure and fire facilities), highly targeted (strictly in accordance with the system requirements to design).

5 Conclusions

With the aid of Internet of things to monitor the fire facilities' status and possible fire disaster, so that all the useful information can be easily acquired. While taking advantage of the 3D GIS to simulate fire occurrence, development and people's response in VR to achieve training, assessment and improving the ability of firefighters, it can also generate an auxiliary emergency plan to analyze the fire, make action plans and real-timely get fire equipment, vehicles' status, firefighter's action tracks etc. By making the indoor electronic maps, further more using indoor positioning technology

to get real-time location information of indoor personnel, thus greatly facilitates Fire Rescue. Based on this, to formulate the digital emergency plan for all types of enterprises is very important, and it helps to make the fire rescue and fire training more scientific , intelligent , virtual .

6 ACKNOWLEGEMENT

This work is jointly funded by the projects No. 2011FU125Z24 from Chinese Ministry of Science and Technology and the project of Special Industrial Development and Application of Satellite (Fire Emergency Rescue Application Platform Based on High-Precision Positioning Seamless Indoor and Outdoor) from National Development and Reform Commission.

Keywords: Urban Emergency Management System; Framework Model; Crisis Evaluation; Policies.

Abstract. In order to tackle the insufficiency of policies of urban crisis management and conform to the ability to deal with urban crisis, it asks to establish a comprehensive emergency management system. Under this circumstance, this paper puts forward a general framework of urban crisis, analyzing the corresponding key technologies of the system and founding a risk rating evaluation model of urban natural calamities based on the improvement of projection pursuit so as to offer scientific basis to the effective establishment and application of the evaluation system and the enhancement of the abilities to urban disaster emergency.

Introduction

To build an efficient and unified urban emergency management system is an inevitable choice for a city to enter the modern management. The possible influences of unexpected public events on a city with a larger scale are great, so it needs a more sensitive and efficient emergency management system. In many a city in developed countries, urban emergency management system has become an integral part of people's daily life, even having been the symbol of urban management level. Therefore, how to establish an efficient urban emergency management system has become an urgent task for urban managers. The paper focuses on the establishment of urban emergency system, has proposed a general framework model of urban emergency management system based on three dimensional cube structures, and effectively controls urban emergency management taking into account the risk rating evaluation model of urban natural calamities based on the improvement of projection pursuit.

Analysis of the Construction Model of Urban Emergency Management System

Urban emergency management system is a multi-level, multi-sectoral and multi-functional complicated giant system with dynamic changes. Essential factors within the system generate multiple feedbacks and constitute compound system with some structure and function by interaction, interplay, interdependence and mutual constraint during the circulation and exchange of materials, information and energy. Urban emergency management information system adopts advanced network technology, computer technology and multimedia technology. The system performs functions such as aided policies of emergency command and scientific mobilization of emergency resources through the collection, transmission, storage, settlement and analysis of all kinds of data on unexpected public events. According to the general framework model of urban emergency management system and the features of urban emergency management, the general technology framework model of urban emergency management system is put forward.

General Frame Diagram of Construction Model of Urban Emergency Management System

Technology framework model of urban emergency management system consists of five layers: network communication layer, information resource center, application supporting platform, business application platform and integrated information gateway. Before the sudden public events occur, the system can assist the emergency management personnel in the preparation of emergency work and exert the functions of real-time monitoring and warning; when the unexpected public events happen, the system can swiftly provide emergency commanders and decision makers accurate and detailed resource information and status of events. It also can assist decision makers in making emergency decision by the application of intelligent decision-making technology so as to execute scientific

commanding mobilization. After the unanticipated public events, the system is able to aid the emergency management personnel to return to the emergency works.

Analysis of Key Technology of Urban Emergency Management System

The Establishment and Renewal of Plan Library of Urban Emergency Management System: Experts formulate a series of reasonable emergency plans by means of some forming process and methods of plan, including plans made under stimulated situation and past successful cases. Then they build plan library in virtue of computer information system. Plan library engages in the storage and organization of plans formulated under stimulated circumstance and past successful cases. Each plan includes complete description of related issues and solutions. The addition of a new plan accompanies the establishment of index of its main features. Based on that, the establishment and renewal of plan library are realized by the management system of plan library. The management system of plan library is mainly composed by five sections, shown on the Figure1. The whole system is based on the comprehensive information bank, it will exert sort management on plans within plan library according to the characteristics of emergencies and offer functions such as the unload, download, inquiry and renewal of plans.

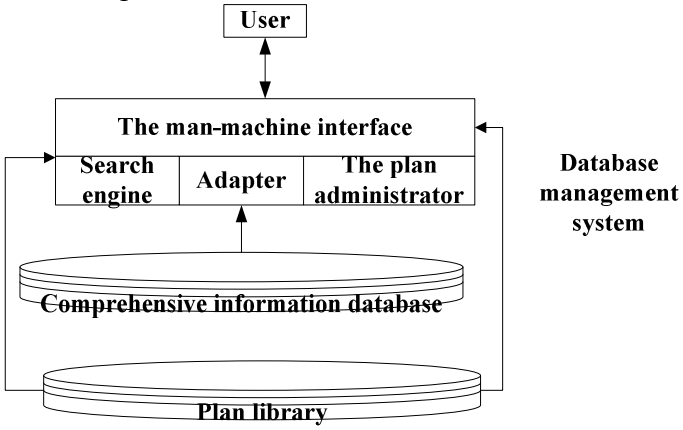

Figure1 Working Diagram of Management System of Plan Library

Risk Rating Evaluation Model of Urban Natural Calamities Based on the Improvement of Projection Pursuit: The basic principle of projection pursuit is to project high-dimensional (namely m dimension) data on the subspace of low dimension. The projection space that can reflect features of high-dimensional data should be the rank dimension of high-dimensional matrix, set as K dimension ($1 \leq k \leq m$), that is to say, when high-dimensional data is projected on its space of rank dimension, the space is the one that losses the least original data information. Furthermore, when the dimension of projection space is below k, the amount of information reflected original data gradually decreases with the reduce of dimension. Immune Clonal Selection Algorithm (ICSA) optimizes the projection .direction in order to have access to divisible low-dimensional data. Details are shown in document [5].

Assuming the sample set of each index value within the evaluation rating table as {x*(i, j)/i=1, 2, 3, …, n;j=1, 2, …, m}, where x*(i, j) means the i-th sample and the j-th index value while n and m refer to the number of sample city and the amount of evaluating indicators respectively. To eliminate dimension of each index value and unify change range of each index value requires non-dimensional treatment. Projection index is founded by combining the projection pursuit model built by Firedman-Tukey:

$$Q(a) = S(a) * d(a) \quad (1)$$

Compared to the three-dimensional space, the amount of the lost information on the one-dimensional space is less in the course of lowering dimension. Under that situation, the paper selects to lower to the three-dimensional space due to the clustering algorithm of projection pursuit of ICSA. Class separation distance and class density of projection index are referred to S(a) and d(a) respectively while three projection directions of three-dimensional space are indicated as x, y and z, so we have:

$$S(a)=\{\sum_{i=1}^{n}[1-\frac{dx_i\times d\bar{x}+dy_i\times d\bar{y}+z_i\times d\bar{z}}{\sqrt{(dx^2{}_i+dy^2{}_i+dz^2{}_i)\times(d\overline{x^2}_i+d\overline{y^2}_i+d\overline{z^2}_i)}}]/n\}^{\frac{1}{2}} \quad (2)$$

dx, dy, dz refer to the projection characteristic value of x, y, z on three-dimensional space. $d\bar{x},d\bar{y},dz$ are the mean value of dx, dy, dz. If S(a) is bigger, distances between classes are bigger, that is to say, on-class degree of association of original data is smaller. Just like Formula (3), correlation coefficient of any two in-class data is taken as rrk. The bigger rrk is, the denser in-class distribution is. S(rrk-R) is unit speed function. R<rrk,S(rrk-R)=1. Under other situation, values are 0.

$$d(a)=\sum_{i=1}^{n}\sum_{k=1}^{n}r_{rk}s(r_{ik}-R)$$
$$r_{rk}=\frac{dx_i\times d\bar{x}+dy_i\times d\bar{y}+z_i\times d\bar{z}}{\sqrt{(dx^2{}_i+dy^2{}_i+dz^2{}_i)\times(d\overline{x^2}_i+d\overline{y^2}_i+d\overline{z^2}_i)}} \quad (3)$$

The theory of projection index proposed by Friedman-Tukey is the same as the clustering measurement criteria, which means class separation distance and class density are inspected under no supervision. In ICSA, projection index will be the object function counting the antibody affinity. The computational process is displayed below:

$$f=\max Q(a)$$
$$||(a)||=1 \quad (4)$$

In the one-dimensional to three-dimensional projection space of pp algorithm, the paper chooses three-dimensional space so it has three projection directions: ax, ay, az. Hence, ICSA has to successively optimize three groups of initial population generated randomly, that is, ax(k), ay(k), az(k). Individual of each population locates in the same place combines a group, able to describe a group of projection direction. Detailed process of operator is shown as follow:

(1) Clonal Operator. Firstly, it is to set clonal scale---q and then take the projection individual of population as antibody and begin cloning. Hence any individual of the population can be cloned for q times. It is shown in Formula (5):

$$\begin{cases}a_x^c=\{a_x,a_{x1},a_{x2},\ldots,a_{xq}\}\\ a_y^c=\{a_y,a_{y1},a_{y2},\ldots,a_{yq}\}\\ a_z^c=\{a_z,a_{z1},a_{z2},\ldots,a_{zq}\}\end{cases} \quad (5)$$

(2) Mutation Operator. The key step of ICSA is mutation. The mutation of ICSA only affects clonal population and save the original population as antibody. In Formula (6), a_x^m,a_y^m,a_z^m means the individual needing mutation among clonal population. The paper selects three projection direction so the mutation way is to choose a direction for hyper-mutation randomly, where α,β,γ are situated among the random number [0, 1].

$$a_x^m=a_x+\alpha,a_y^m=a_y+\beta,a_z^m=a_z+\gamma \quad (6)$$

(3) Selecting operator, calculating the affinity of population and comparing the differences of affinity of the individual after mutation and the original one. If f(axm)>f(ax), then choose axm;; otherwise, it is ax.

Based on the projection pursuit clustering model of Immune Clonal Selection Algorithm, the flow is shown below:

Normalizing high-dimensional data;

Initializing algorithm parameters, ensuring projection direction randomly and forming initial antibody population;

Exerting linear projection on normalized high-dimensional data;

Optimizing projection index by the application of Immune Clonal Selection Algorithm, achieving the most optimal projection direction;

Linearly projecting high-dimensional data on the most optimal direction, gaining three-dimensional space;
Exerting K-Means clustering on three-dimensional space;
Getting the distance between each point of three-dimensional space and the clustering centre point regarded as the evaluation value.

Experimental Verification

The paper selects IRIS data set and SONAR data set for the test. IRIS data set is four-dimension and has 150 samples while SONAR is sixty-dimension and has 208 samples. One of the data set belongs to high-dimensional data and the other is low-dimensional data. Moreover, the gap of the capability of samples is rather small; hence it applies to the verification of the effect of two kinds of clustering algorithm on high-dimension and low-dimension. After testing, results we have are shown on Figure2 and Figure3:

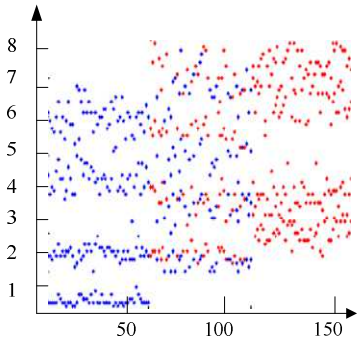

Figure2 PP Clustering of IRIS Data Set

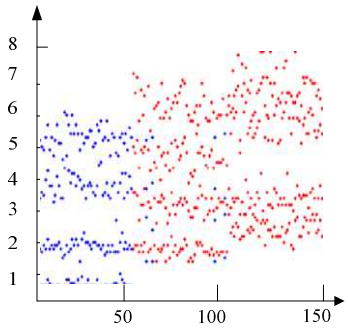

Figure3 K-Means Clustering of IRIS Data Set

The abscissa of clustering diagram represents the types of sample while the ordinate is the value of each dimension of the sample, red and blue being the types of clustering. It is shown that the accuracy of the PP clustering of high-dimension is rather high. So is low-dimension. Compared to the accuracy of data of UCI data set derived from the direct use of K-Means clustering algorithm, the accuracy will become higher by the application of K-Means clustering algorithm after having lowered its dimension.

Conclusion

To build an efficient and unified urban emergency management system is an inevitable choice for a city to enter the modern management. The possible influences of unexpected public events on a city with a larger scale are great, so it needs a more sensitive and efficient emergency management system. The paper studies framework model of urban emergency management system, building a risk rating evaluation model of urban natural disasters. It lowers high-dimension to three-dimension by projection pursuit and during that optimization procedure, it replaces Genetic Algorithm with Immune Clonal Selection Algorithm, accelerating the convergence speed and avoiding local optimization and finally proves the validity of the model been improved.

Keywords: grey clustering, logistics supply chain, inventory information management

Abstract. The supply chain information management of logistics has become an important method to enhance its competitiveness. The inventory information management and application of the logistics supply is researched based on grey clustering decision-making methods. The inventory theory and methods are studied firstly, and the fuzzy mathematics and grey system theory are used to solve the classification problem. The electronic industry logistics supply chain is taken as the example, the inventory information management problem is solved. The inventory information management theory is improved in this paper, and it can more accurately reflect the market situation, it provides the reference for the classification of inventory information management in logistics supply chain.

Introduction

With the rapid development of logistics industry, the supply chain has played an increasingly important role. The information management of supply chain is becoming as the focus of research in the logistics industry. The complete process of supply chain is the raw material management to the products after each link in the production chain. Through distributors, retailers and transport business process, the products are sent to the customer finally[1]. In the electronic industry, the logistics supply chain research has attracted more and more attention today. The inventory information management is an important part of the whole electronic industry supply chain, and it has an important function in various activities of security and smooth management[2]. Especially, the electronic industry is a special industry with special characteristics, a certain amount of goods should meet the customers with nice goods quality and services, and it can greatly shorten the delivery time for meeting the needs of customers. However, inventory goods need to take great risks, the risks mainly contain the payments and inventory costs risk, as well as the risk of backlog of goods. So the study of inventory classification and the implementation process of chain information management have great theoretical and practical significance. Based on the above analysis, this paper takes the electronic industry logistics supply chain as the research object, the inventory information management of logistics supply chain is researched, and the relative algorithm is designed. The customer satisfaction is taken as the basis, and the fuzzy mathematics and grey system theory are used for solving the classification problem of inventory information management[4,5]. The research result has good application value in supply chain optimization and inventory information management.

Problem description

The electronic industry is special industry, which makes the inventory is becoming more and more important in logistics and supply chain management. In the supply chain, logistics transport process changes the state space of goods, and inventory is changed the goods time state. It plays an important role in modulating every link of the production, and the relationship between production and marketing is adjusted. In addition, it also can greatly shorten the delivery time, reduce costs and increase profits. However, in the electronic industry, different departments have the different attitudes, and transportation procurement can reduce cost and increase inventory levels, inventory information management departments tend to reduce inventory levels. The cost of inventory goods amount is reduced. It shows that inventory information management departments and other

departments have the conflict. There is contradiction between investment of inventory levels and customer satisfaction. With the development of logistics information management technology, the enterprises can solve this problem, and the coordination between the various departments and clients is implemented.

So far, ABC classification method is often used in the inventory information management technology, the method can limit the enterprise resources with biggest effect, at the same time, the goods classification is obtained, and the information management system is designed. Specifically, more and more human and material resources can be put into the relatively expensive items, and the information management is taken. Therefore, the goal is to reduce costs, ensure that the inventory of goods can be managed automatically. However, its defect is obvious, such as a good may itself is not precious materials, we pay no attention to the inventory quantity, but the goods are indispensable parts of the production process. So it is possible result in interruption of production chain and sales chain. It causes greater losses. In addition, this method is subjective without taking into consideration the quality, the inadequate supply and many practical situations are missed.

Model construction

A.Model assumption

The significant characteristics of logistics supply chain is to realize the combination of logistics and human beings, therefore, in the classification of goods inventory information management, how to divide the product, how the allocate the resources, these problems have very important meaning. In the classification of products, involving many different kinds of evaluation index, such as the shortage of supply, customer satisfaction, these indicators are vague and grey, in order to exact these indicators as features, the feature extraction algorithm is researched, and the inventory management of the fuzzy classification is obtained. The gray system theory is introduced in the storage management of goods, if there is a new storage, and the inventory information is counted according to the classification.

In the logistics supply chain, there are many concepts is difficult to define, especially in the electronics service industry, the satisfaction degree of customer is difficult to quantify, and the evaluation of products is difficult to quantify, the indicators are difficult to quantify, they are vague, so the grey clustering decision method is used to analyze the data.

B. Construction of grey clustering decision model

Grey clustering analysis methods can be divided into two types as grey clustering and grey whitening weight function clustering. In the logistics supply chain, mainly using grey clustering method is to simplify the classification system, similar factors is classified. The whitening weight function clustering method is studied to check the goods category according to the standard set before, and the scientific and reasonable classification of the inventory of goods logistics in supply chain is studied.

a.Establishment of the evaluation matrix

First, we need to determine the decision object of supply chain, decision criteria and decision grey. In this paper, assumed that the decision-making object is $i \in I = \{1,2,3,.....m\}$, the decision index is $j \in J = \{1,2,3,.....n\}$, the decision grey classification is $k \in K = \{1,2,3,....w\}$, when the gray is $k = 1$, it means that the supply chain is good, when the decision grey $k = w$, it is bad. According to the decision criteria and decision object, establish the sample matrix $A = \left(x_{ij}, i \in I, j \in J\right)$, where, the sample data.

Because the data sample has different indicators with different dimension, the difference is big, in order to evaluate sample data further, the evaluation matrix is standardized, the formula is:

$$x_{ij}=\begin{cases}\left(d_{ij}-\min\limits_{i}d_{ij}\right)\Big/\left(\max\limits_{i}d_{ij}-\min\limits_{i}d_{ij}\right)\\ \left(\max\limits_{i}d_{ij}-d_{ij}\right)\Big/\left(\max\limits_{i}d_{ij}-\min\limits_{i}d_{ij}\right)\\ 1-\left|d_{ij}-f_i\right/\left|\max\limits_{i}\left|d_{ij}-f_i\right/\right|\end{cases} \tag{1}$$

b. Establish the model

According to the grey decision $k\in K=\{1,2,3,....w\}$, assumed $f_j^k(*)$ is the whitening weight function of clustering index j about k gray class. If the clustering index j is independent on k grey clustering weight, namely clustering weight of clustering index j is $\eta_j(j=1,2,,,,,n)$, and $\sum_{j=1}^{n}\eta_j=1$,then:

$$\eta_j^k=\frac{\lambda_j^k}{\sum_{j=1}^{3}\lambda_j^h},\ \sigma_i^k=\sum_{j=1}^{m}f_j^k(x_{ij})\bullet\eta_j^k \tag{2}$$

The formula as above represents clustering weight of *k* gray about the clustering index *j*, the formula σ_i^k is the clustering coefficient of clustering object *i* belongs to the *k* gray class, after normalization process, the clustering coefficient vector is: σ_3^1, σ_3^2, σ_3^3 ,When $\max\limits_{1\le k\le w}\{\sigma_i^k\}=\sigma_i^{k*}$, it means that the object *i* belongs to the gray *k*.

Example and experiment of the model

In this paper, the electronic industry supply chain is taken as an example for study, the inventory states are taken scientific classification of three kinds of product, the classification of the goal is to reduce the cost, increase profit, and it can be classified from the importance of inventory information management and the cost of products. Based on the data collecting and collating information, the index sample value X_{ij} (i=1.2.3; j=1.2.3;) of i th product is obtained. Therefore, according to the matrix A , we can get the indexes such as price of the products, shortage condition, and customer satisfaction etc, the of can get the, the whitening weight function is shown as follows:

$$A=(1-\lambda t)(1-t)^3,\ A=B_{40}+\tfrac{1-\lambda}{4}B_{41},\ B=\tfrac{3+\lambda}{4}B_{41}+B_{42}+\tfrac{3+\lambda}{4}B_{43},\ C=\tfrac{1-\lambda}{4}B_{43}+B_{44} \tag{3}$$

Analysis as above, we can get: $\sum_{i=0}^{2}b_{2i}=A+B+C=\sum_{i=0}^{4}B_{4i}=1$

Because $\sigma_i^k=\sum_{j=1}^{m}f_j^k(x_{ij})\bullet\eta_j^k$, while $i=1$, we can get:

$$\sigma_1^1=\sum_{j=1}^{3}f_j^1(x_{ij})\bullet\eta_j^1=f_1^1(x_{11})\bullet\eta_1^1+f_2^1(x_{12})\bullet\eta_2^1+f_3^1(x_{13})\bullet\eta_3^1=0.74$$

When $\max\limits_{1\le k\le 3}\{\sigma_1^k\}=\sigma_1^1$=0.74, the results are: $\max\limits_{1\le k\le 3}\{\sigma_2^k\}=\sigma_2^2$=0.74, $\max\limits_{1\le k\le 3}\{\sigma_3^k\}=\sigma_3^1$=0.59

Result analysis

From the above results, with the analysis of the first and third products, it shows that it is a very important grey, while the second product is an important grey. In addition, according to the clustering coefficient, even it belongs to the uniform grey, first products and third products also have the difference, if the segmentation of grey is taken, we will obtain different results. This shows that the grey clustering decision method can improve the efficiency of the inventory information management in supply chain.

Conclusions

In this paper, inventory information management of logistics supply chain is taken as the research object, the inventory theory and related methods are discussed, and the fuzzy mathematics and grey system theory are used to solve the classification problem. The inventory information management theory is improved, and it can reflect the field situation comprehensively. The factors of the customer satisfaction degree and shortage of goods are obtained, and the corresponding improvement measures are proposed. The research result has good application value in practice.

The design of transaction condition expert evaluation system for the logistics online retailers

Geng jihua

ShanDong labor vocational and techncal college, Shandong jinan 250022

Keywords: Electronic-commerce; online retailer; evaluation system

Abstract: With the rapid development of Electronic-commerce, the traditional logistics industry is gradually combined with Electronic-commerce which fully opens the era of logistics online retailer. The basic network platform is the basis of the logistics online retailers. This paper focuses on the establishment of the Electronic-commerce platform with architecture and design techniques. The platform can ensure the stability, efficiency, security, redundancy and scalability of the evaluation system for the logistics industry and economic conditions of the online retailers.

1 Introduction

The logistics industry, integrating the complex new industries such as warehousing industry, freight forwarding industry, has played a crucial role in China's economic development, which also illustrates the national level of comprehensive modernization of a country[1~2]. At present, the development of China's Electronic-commerce logistics information platform stay at the initial stage[3~5]. The logistics online retailers build the logistics Electronic-commerce platform which automatically identify and communicate between human and machine or machine and machine. It can also provide comprehensive awareness, online trading and intelligent recognition which promotes the rapid development of logistics Electronic-commerce[6]. This paper focuses on the establishment of Electronic-commerce platform through architecture design techniques which can ensure the stability, efficiency, safety, redundancy and scalability of the valuation system for the logistics industry and economic conditions of the online retailers.

2 The expert evaluation system model for logistics online retailers

2.1 The online retailer platform model design based on Internet of Things

The logistics Electronic-commerce platform based on Internet technology is faced to the logistics companies, suppliers, manufacturers, retailers, partners, customers, governments and banks. With the Internet technology, the platform can integrate the logistics resources based on logistics market and operation main bodies, optimize the social logistics resource configuration, reduce social logistics costs and provide professional online logistics throughout all aspects of the logistics operation and other value-added online services. The platform is based on the SOA structure and three-tier structure of Internet of Things including six layers of logistics resource layer, data acquisition layer, the network communication layer, data layer, application layer, and user layer.

2.2 The function module analysis for logistics online retailer information service platform

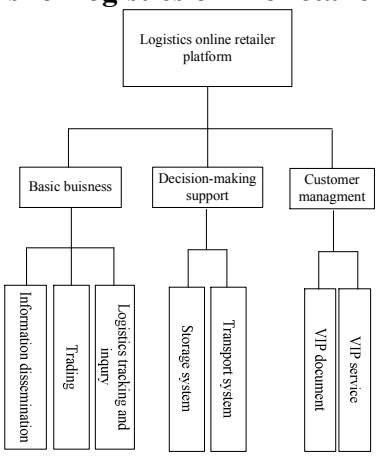

Fig. 1 The function modules for the logistic online retailer service platform

The logistics online retailer information service system mainly consists of three functional subsystems-basic business system, decision support system and customer management system. The basic business system is mainly to maintain the basic business for the logistics online retailer information service system including information dissemination, trading, logistics tracking and inquiry functions. The decision support system provides decision-making support for the logistics online retailer information service system and optimization for many aspects of the logistic service, such as warehouse management and transportation management. The customer management system is a bridge between the system and customers and customer including VIP file management and VIP services. The specific function modules of the system are shown in Fig. 1.

2.3 Evaluation computation equation

The classification super surfaces of the risk transaction potential factors in the Support Vector Machine optimization problem are normalized. Let $\Delta = 1$ and the corresponding compress coefficients are u and k respectively. The corresponding support vectors are expressed by

u·x+k=1, if y=1

u·x+k=-1, if y=-1 （1）

The distances between the support vectors to the classification super surfaces of the potential factors are denoted by 1/||u||. The linear programing function with some constrains is used to classify the potential factors as the equation (2).

$$\min_{u,\ k} \frac{1}{2}\| u \|^2$$

$$z.p.y_i(u \bullet x_i + k) \geq 1,\ \ i = 1,\ \ \ldots,\ \ h. \qquad (2)$$

Based on the optimal principles, the optimal solutions of the objective function with constrains can be obtained. The Lagrange function is described with equation (3).

$$H = \frac{1}{2}\| u \|^2 + \sum_{i=1}^{h} \beta_i [1 - y_i(e \bullet x_i + k)] \qquad (3)$$

In the equation, $y_i(u \bullet x_i + k) \geq 1$ denotes the constrain, $\beta_i \geq 0$ denotes the Lagrange product factor with constrains. With KKT norms, there are:

$$\frac{\partial}{\partial u} H = u - \sum_{i=1}^{h} \beta_i y_i x_i = 0 \Rightarrow u = \sum_{i=1}^{h} \beta_i y_i x_i$$

$$\frac{\partial}{\partial u} H = \sum_{i=1}^{h} \beta y_i = 0 \qquad (4)$$

With Wolf couple principles, the Wolf couple problem with optimization can be expressed by

$$\max_{a} u(\beta) = \sum_{i=1}^{h} \beta_i - \frac{1}{2} \sum_{i,j=1}^{h} \beta_i \beta_j y_i y_j x_i \bullet x_j$$

$$z.p. \sum_{i=1}^{h} \beta y_i = 0. \beta_i \geq 0, i = 1,\ \ \ldots,\ \ h.. \qquad (5)$$

The optimal solutions of the previous equation can be obtained in order to obtain the corresponding super surfaces. If β^{Δ} denotes the optimal solution, β^{Δ} is usually 0; If β^{Δ} is not 0, the corresponding vector x_i is support vector and the linear set for training sample vectors is $u^{\Delta} = \sum_{i=1}^{h} \beta^{\Delta}{}_i y_i x_i$. The support vector of x_ii is randomly selected in order to determine k^{Δ} which is $k^{\Delta} = y_i - u^{\Delta} \cdot x_i$. Finally, the obtained evaluation function is described in equation (6).

$$g(x) = \log al(u^{\Delta} \bullet x + k^{\Delta}) = \log al(\sum_{i=1}^{h} \beta^{\Delta}{}_i y_i x_i \bullet x + k^{\Delta}) \qquad (6)$$

In the equation, log al（·） denotes the sign function with

$$\log al(p) = \begin{cases} 0 & p < 0 \\ 1 & p \geq 0 \end{cases} \qquad (7)$$

By the equation (6), the potential factors can be classified and the classes are used to evaluate corresponding risk conditions.

3 Simulation experiments and results analysis

Take some large scale logistic Electronic-commerce trading platform as an example. The local classification for the logistic Electronic-commerce trading with volume larger than 300,000 is described in Table 1.

Table 1 The classification of main risk factors for a local logistics enterprises

Score	Rank	Transaction volume	Number of transaction	Feedback
0-0.5	Risk out of control	30-50	800-500	0.8-1
0.5-1.2	Major risk	50-60	500-400	0.8-0.9
1.2-1.5	Medium risk	60-70	400-300	0.8-0.6
1.5-2.6	Normal risk	70-50	300-200	0.6-0.7
2.6-3.4	Credit pass	50-80	200-100	0.4-0.6
3.4-4.0	Credit medium	100-150	100-80	0.6-0.5
4.0-4.5	Credit good	150-200	80-50	0.1-0.12
4.5-5.0	Credit excellent	Above 200	50-20	Below 0.1

These factors reflect the area level segmentation of the main relative factors in the logistic online retailers' transaction processes in which the segmentation approaches are random. Therefore, the proportional weights in the overall logistic risk assessment model can describe the fluctuation conditions in the main body. The objective factors have strong operational capabilities and the risks caused by the relative constrain factors are strongly objective which can be quantitatively analyzed to ensure the stability of the overall environment of the E-commerce transactions as shown in Fig. 2.

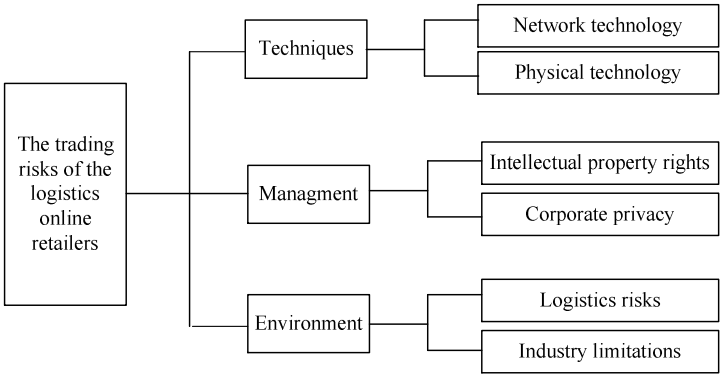

Fig. 2 The trade risks for the logistic online retailers

The comparison experiments evaluate the advantages of the proposed method. The traditional neural network algorithm is used as comparison object. The mean relative errors are used as the experimental evaluation index and results are described as follows.

Table 2 The comparison of prediction performance with different algorithms

Prediction model	MSE	MAE
BP neural network	8.656	0.353
RBF neural network	6.665	0.445
Proposed method	2.433	0.035

The predication results in Table 2 illustrate the proposed algorithm has advantages in the computation speeds and predication accuracy compared with the traditional algorithms because the proposed method can judge the classification penalty factors which can classify different penalty factors with categories. This overcomes the defects of traditional methods which prevent the defects of local minimum and slow convergence speeds in the traditional Support Vector Machine methods.

4 Conclusions

In the Internet era, the online retail platform for the model logistic enterprise is imperative which is beneficial to maximize efficiency and profits. The trading condition expert evaluation for the electronic trading platform is a new technology that can detect potential malicious transactions and reduce harmful transaction. In this paper, the accumulative data during the Electronic-commerce is effectively used to predict future data and evaluate the transaction risks for different level of customers in the future trading. The experiments illustrate the proposed Electronic-commerce risk predication method can predict the security conditions in different online trading with high accuracy which overcomes the shortcomings of traditional methods and it is more suitable for the current network transactions.

Application of visual correction on physical training

Zhai Qiang

Physical Education College of Luoyang Normal University Henan Luoyang 471022 China

Keywords: irregular; single frame; moving images; dimensional posture; correction

Abstract: A method is presented for three-dimensional motion posture correction employing Fuzzy kernel estimation and affine transformation. As selecting human moving node by a visual sensor and smoothing single frame image with irregular motion, noise interference is reduced. Based on principles of perspective and affine transformation, adjustment strategy of three-dimensional posture is deduced for irregular single-frame motion picture. In addition to determination of motion picture rotation, accurate correction of irregular single-frame motion picture is proposed. Experimental results show that, under different noise conditions, the algorithm corrects posture of a three-dimensional moving image accurately and presents strong anti-noise performance.

1 Introduction

With gradual development of machine vision principle and direction of high-speed, high-precision, high sensitivity sensors, application of monocular vision technology continues to expand, which is hot issues in aerospace, industrial automation, artificial intelligence and other fields[1,2]. Traditional three-dimensional posture correction method[3] is mainly based on analyzing different characteristics of frames. As confusing with noise on non-significant edge, characteristics of irregular single-frame motion image is interfered by noise factors to reduce quality of image characteristic. For this reason, it is impossible to correct posture effectively, there is big drawbacks for tradition method[4,5].

2 Correction of three-dimensional posture

2.1 Selection of physical node

In process of three-dimensional human motion, the most important matter is to collect human characteristics of key nodes. Typically, it is need to divide physical body for motion analysis into several subareas, and set the subareas as a child node of the tree structure. Based on these child nodes, virtual physical body is established to surround tree hierarchy. The hierarchy is searched from a child node of the top; according to top-bottom sequence, all the child nodes constructs a linear collection and calculates bounding box of the linear sets, until root node is obtained. These results are described in Figure1:

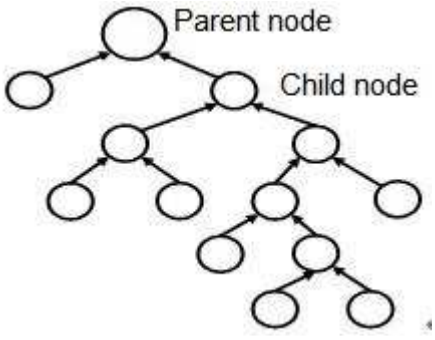

Figure 1 Physical motion characteristics of hierarchical bounding tree

Since it is prone to come into various non-normal contacts between different parts of torso section, independent analysis of these portions are needed. Using the following Figure2, tree hierarchy is described by building all the joints in the body of each tree as a child node:

It is capable of collecting human motion data and capturing body movement, by image-sensing instruments and trajectory tracking device. In data collection, miniature sensors are installed on joints of physical body, which transfers the case of joint motions to control terminal. However, due

to spatial sensor can not capture position of body motion, trajectory tracking device is installed to obtain trajectory of each joint.

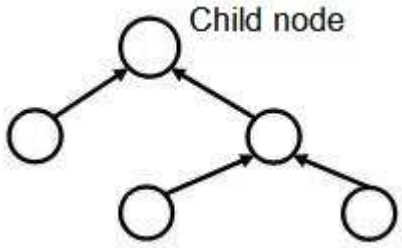

Figure 2 Tree hierarchy of torso section

The relationship between bending movement of physical body and data collected of image sensor can be described by the following equation:

$$b = \frac{\max_b - \min_b}{W_p} * W_d \quad (1)$$

Where b is bending motion of the joint in the body, $\max_b$ is the maximum bending of joint, $\min_b$ is the minimum bending of joints, W_p is the data collected by joint sensor, W_p' is correction factor of data collected by sensor joint. As can be represented by the following formula,

$$W_d = \frac{W_p - U_{\min}}{U_{\max} - U_{\min} \times g} \quad (2)$$

Where $U_{\max}$ is used to describe as upper limit of flexion degree, $U_{\min}$ as lower limit, g is magnification of image data corresponding to sensor acquisition.

2.2 Three-dimensional posture correction method based on affine transformation

When the midpoint of image starts rotated transformation, the transformation matrix can be used to rotate the tilting movement of the image to adjust new three-dimensional posture. As the rotational transformation matrix for adjusting the tilt of the motion picture, the data is summarized into two cases as follows:

（1）If three-dimensional motion posture of the image is tilted to the left, adjust the formula as：

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} \cos(\theta_1) & -\sin(\theta_1) & 0 \\ \sin(\theta_1) & \cos(\theta_1) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} \quad (3)$$

Wherein, x, y respectively represent the two-dimensional coordinates of the original image pixel, x', y' respectively represent the two-dimensional coordinates of the adjusted pixel. Corresponding to the adjustment coordinate x', y' and x, y coordinates of the pixel, a new motion picture is reformed as adjusted three-dimensional image.

（2）If three-dimensional motion posture of the image is tilted to the right, adjust the formula as：

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} \cos(-\theta_1) & -\sin(-\theta_1) & 0 \\ \sin(-\theta_1) & \cos(-\theta_1) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} \quad (4)$$

In the above formula, θ_1 means angle of image rotation transformation. Depending on the angle deviation, correction is completed.

3 Experimental Analysis

In order to verify effectiveness of this method, relevant experimental analysis is needed. Experimental analysis of traditional methods and corrected method is proposed under different experimental conditions. The three-dimensional motion posture assessment is standard evaluation criteria of image correction method as this paper describes: root mean square error (RMSE), which will assess error between corrected image and original image, the mathematical model is:

$$RMSE = \sqrt{\frac{\sum_{i}^{n} (x_i - y_i)^2}{n}} \tag{5}$$

Where, x, y represent the original image and the corrected image. As the corrected image is similar to the original image, RMSE value is small. In experiment, random noise is added to motion blurred image. As noise gain is defined as the maximum of noise, noise value is [0, noise gain]. When correcting image, set decay rate of the threshold t as 0.1, set regularization parameter γ=10 , λ=0.002 , the image block size as $[6\times6]$.

Figure 3 depicts the effect of noise magnitude on correction results. As the noise intensity increases, RMSE for correction of the image increases slightly. RMSE increase of this method obtained from corrected image, is slower than the conventional image. The method described herein significantly reduces the noise effect.

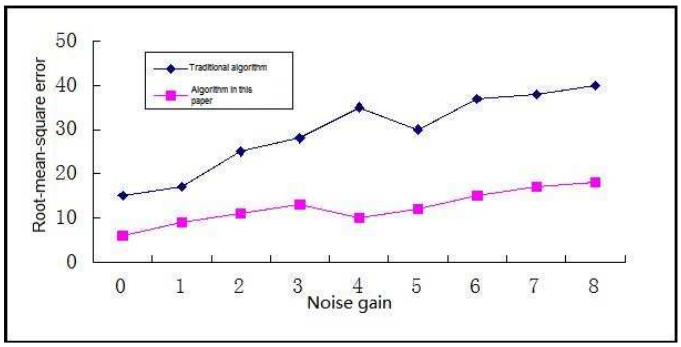

Figure 3 Image correction between methods in different noise gains

4 Conclusions

This paper presents an application of three-dimensional posture correction method based on fuzzy kernel estimation and affine transformations. Combining with the determination of the motion picture rotation, 3D pose of the moving image is adjusted to achieve an accurate three-dimensional motion correction of irregular posture. Experimental results show that, under different noise conditions, the algorithm corrects posture of a three-dimensional moving image accurately and presents strong anti-noise performance.

Monitoring system of High-power project control network data storm under non-uniform format

LIU Jin[1,a], Dai Yu[1,a], CHEN Jia-jia[1,a]
[1]College of Economics and Management, ChongqingUniversity of Posts and Telecommunications, Chongqing 400065

[a]Liujin@cqupt.edu.cn

Keywords: project control system; network data; monitoring system

Abstract. By analyzing the structure of high-power data project control monitoring system under non-uniform format, the control model and status of the system are introduced. Direct at the requirements of data acquisition machine information exchange and the complete deployment for project control system, medium flow and pressure control, it not only improves the performance of the system, but also makes the system reliable, flexible and easy to expand. Running results show that the proposed system for the realization of high-power project control system data monitoring is valid, the data transmission efficiency significantly higher than traditional serial communications.

Introduction

Project control system is the core part in most large equipment and with complex technical. But because many causes of failures cannot be diagnosed through the device running after the unit shut down [1]. Fault diagnosis at equipment downtime can increase the difficulty of fault detection, fault diagnosis and determination, which delays fault finding, diagnosis and treatment, seriously affects the normal use of the device, and may cause significant economic losses [2]. Establishment of project control system diagnostic system will be very necessary, it can provide a digital signal processor for fault diagnosis of project control system, is a network processing unit which can make high-speed real-time processing when the analog signal transfers into a digital signal [3]. Chip is a high-speed dedicated microprocessor which developed based on ultra large scale integrated circuit technology and computer technology, with powerful computing capabilities and high-speed data transfer capability, can easily handle real-time signal which is main based on computing and not allowed to delay. It can achieve the signal acquisition, conversion, filtering, valuation, enhancement, compression, recognition and other treatments [4, 5].

This paper presents a study design for data monitoring system of the project control system under non-uniform format which is aim at real-time monitoring to power temperature and other parameters of high-power project control system, as well as on-site environment. And it can be transmitted through existing communication networks. All of these can lay a good foundation for fault diagnosis of equipment [6].

Data Monitoring Principles

A.Traditional data monitoring system

MWp standard sub-square building program is used in traditional data monitoring system which is convenient for the construction of project control systems and operations management. Data monitoring system is achieved by making a single configuration data acquisition cabinet in the center control system. The center control system includes data acquisition unit, the ring network switches and other devices. Weakness of the traditional approach is that: 1) Communication Manager is easy to damage, it will cause serious crashes of data monitoring system, affect the reliability of the overall operation of the system; 2) the amount of transfer equipment is too much, communication structure is more complex, direct resulting high failure rate of the data monitoring system, longer time costing of faults troubleshooting and resolution as well as more labor-intensive. All of these will impact the intelligent management, and increase the operating and maintenance costs.

B.The new data monitoring system

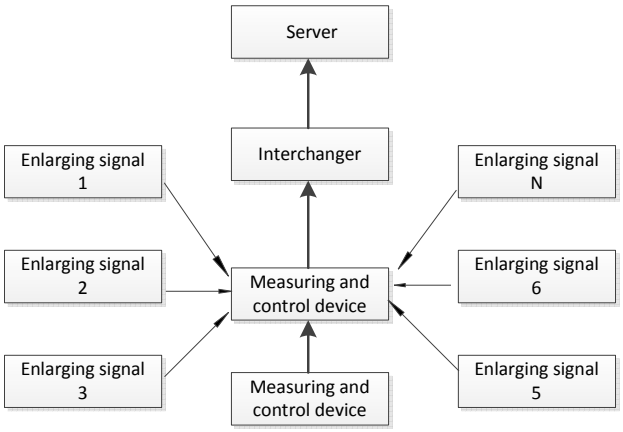

Figure 1 The structure drawing of project control network data monitoring system

With the development of project control networks, it has developed the monitoring and control devices which can make data acquisition, conversion and upload to one. The volume of such devices is small and full-featured. It can achieve the acquisition upload and protection of their own signals, and provide with an integrated data acquisition and expansion interface, which can access a large number of signals and is convenient for all functions such as ring networking, data acquisition, conversion and uploading. Figure 1 shows the structure drawing of project control data monitoring system under non-uniform format based on monitoring and control device constitution.

C.The validation rules of new data Monitoring System

Data validation rules of high-power project control data monitoring system is divided into two categories: 1) correlation validation of single data; 2) the complex correlation verification of multiple data.

For time-continuous data, high-power project control data monitoring platform also uses a more complex but more reliable data verification method, namely the Kalman filtering technique. The state equation and observation equations are:

$$X_k=F_{k,k-1}X_{k-1}+T_{k,k-1}U_{k-1} \quad (1)$$

$$Y_k=H_KX_k+N_k \quad (2)$$

Wherein, X_k and Y_k are the state vector and the observation vector at time k; $F_{k,\,k-1}$ is a state transition matrix; Uk is the dynamic noise at time k; $T_{k,\,k-1}$ is the system control matrix, H_k is the observation matrix at time k; N_k is the observation noise at time k. Pre-estimated by calculating the covariance matrix and the gain matrix and covariance can be applied to detect data mutations. Multi-data complex correlation validation is depended on the management relationship detection between multi-data to test the reasonable of data. Kalman filtering technique is also used to monitor the changes situation of variance in data monitoring platform, which can more accurately judge the bad data.

Simulation and Analysis

the data monitoring platform of a mechanical and electrical equipment is applied as the example. It can be shown in Figure 2 that the design consists of five sub-modules, namely: 1) parameter management module, is responsible for monitoring the parameters setting and managing which is needed for platform; 2) data validation module, is responsible for the verification and screening data to record the check results to log database and provide application calling interface; 3) information monitoring module, is responsible for monitoring the data transfer and calling the interface for data validation check; 4) information notification module, is responsible for sending message according to the monitoring situation; 5) log management module, is responsible for recording the related results of the operation and calibration.

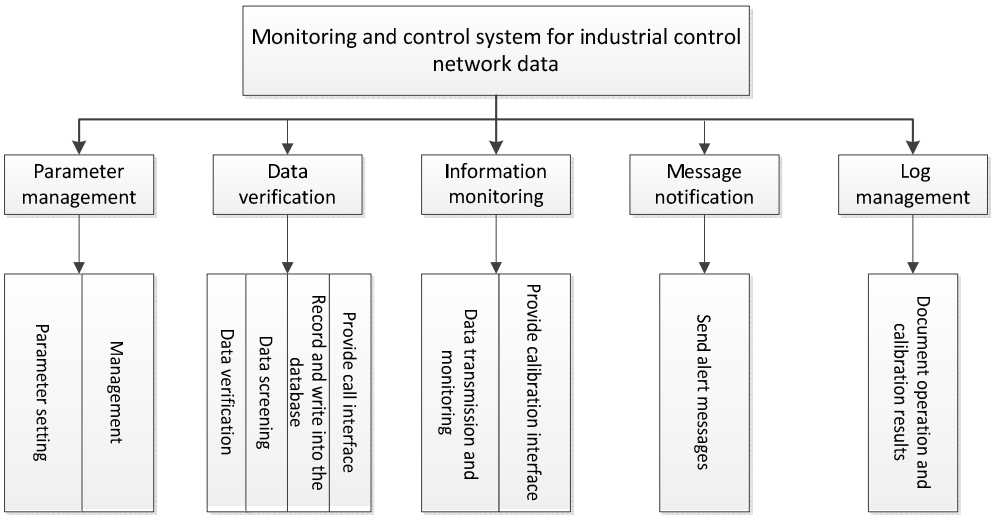

Figure 2 Data monitoring system constitution of project control network

It can be seen from the following three aspects to make conclusion:

(1) construction cost savings

the dimensions of Non-uniform data format project control monitoring device (width × depth × height) is about 200mm × 200mm × 200mm. Compared with the original equipment layout, it can at least reduce 3.2m^2 construction area, and the construction cost of per square meter is about 3,000 Yuan, a total construction costs of 19.2 million of 20 sub-matrices can be reduced.

(2) equipment cost saving

in traditional scenario, data acquisition system is 31,000 Yuan/set, and control devices is about 8000 Yuan/set, rather than the 20,000 Yuan/set of a monitoring device under uniform format project control data monitoring system. That means the equipment cost savings of 380,000 Yuan. As can be seen from the above analysis, the non-uniform data format project control monitoring system can save about 57 million in construction and equipment costs.

(3) The measured frequency, temperature and voltage from a unit will be described as an example in Table 1:

Table 1 The data of frequency, temperature, and voltage in a unit

	frequency	Temperature of generator bearing	Temperature of engine bearing	Enclosure temperature of unit	line voltage AB	line voltage BC	line voltage AC
standard value	200	43.2	41.9	29.8	230	230	230
test value	200	42.8	41.3	29.7	230	229	230
standard value	200	52.6	50.6	28.5	220	220	220
test value	200	51.9	49.8	28.5	221	220	220

From the above data, it can reflect the changes of a unit voltage and other parameters in a process of operation, and we can see that the frequency error is zero, voltage accuracy is 1V, the temperature accuracy degree is 0.1 ℃. All of these can basically meet the resources needs of electrical and mechanical equipment monitoring system.

Conclusions

Data storm monitoring system of High-power project control network under non-uniform format is the basic platforms part of the project control network data monitoring systems. Through a unified management of data validation and alert of all aspects of data processing, it can control and ensure data accuracy and reliability.

To solve the complex data screening and verification problems of project control network data monitoring system through the high-power project control network data storm monitoring system platform under non-uniform format can make effective management for network data. It can ensure the stable and efficient operation of multi-level project control network system, and promote the practical work of project control network data monitoring system. It is also the foundation and

important part of successful construction and efficient coordination operation of multi-level industrial control network.

Keywords: Six Sigma Management; Minitab; DDE; Integrated System.

Abstract: As a systematic and quantitative mode of continuous improvement, six sigma management can thoroughly analyze the problem and solve it based on the data. This article proposed a framework of six sigma management integrated system based on Minitab/DDE and applied it in the practical problem. This system supports us to access the daily production data through the DDE link dynamically and interactively, ensuring the timeliness and validity of project analysis to achieve continuous improvement.

Introduction

Six sigma management is an improving philosophy and method invented by Motorola Inc [1]. The detail implementation mode is DMAIC, which refers to Define, Measure, Analyze, Improve and Control [2]. As a systematic and quantitative mode of continuous improvement, six sigma management can analyze the problem quantitatively based on the data, to identify the process defects and then solve it practically [3-5].

However, the daily production data of enterprise is not only enormous, but it also updates fast. The simple process analysis by statistical software can not ensure the timeliness of data and validity of result. Therefore, the six sigma management integrated system is proposed to create the DDE (Dynamic Data Exchange) link between statistical software Minitab and database, supporting the project analysis by effective real-time data sharing, thus to enhance the competitive advantage in delivery time and multiple varieties of enterprise.

The overall framework of integrated system

Six sigma management integrated system based on Minitab/DDE takes the five stages DMAIC of six sigma improvement mode as the core. The bottom of the system is that Minitab creates DDE link to support the process analysis by the real-time access of production data. And it is applied to the practical project at the top level. Through these, a continuous improved system based on six sigma management is formed as Fig. 1.

(1) By creating a DDE link, Minitab can share the information with any external program which also has DDE function. Click *Edit>Worksheet Links>Manage Links* in Minitab to create a new link and then input *application, topic, item* and some other terms in the popup dialog. The rule of each term is shown in Table 1. Then the real-time and dynamic data transmission between Minitab and DDE containers such as Excel can be realized to support the process analysis of six sigma management.

(2) Unlike the traditional solution “define - improve”, six sigma management has a whole set of improving system, that is, defining the key issue, ensuring the effectiveness of measurement system, analyzing the causes of defects, determining the improving plan, and verifying and maintaining the improvement. Therefore, the application of six sigma management in the practical project can effectively identify the problem thoroughly and achieve continuous improvement.

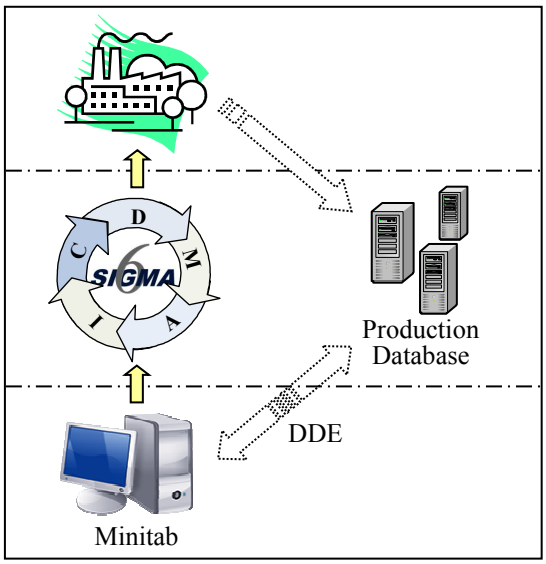

Fig. 1: The overall framework of integrated system

Table 1: Inputting rules of Minitab creating the DDE link

Term	*Explanation*	*Example*
Application	Application name	Excel
Topic	File name (if the file contains several windows, use brackets)	C:\ [Book1.xls]Sheet1
Item	Rows/columns or matrix area imported	R1C1:R8C10
Status	Status of the links	Active/Inactive
Priority	Priority of the worksheets	1~32 (high-low)
Update method	Way of the data transmitting to the worksheet in Minitab	Replace/Append
Anchor Column	Beginning column of the data	1
Action	Anticipated operations after the data transmitting to the Minitab	Update data and execute commands/ Update data only/Execute commands only
Commands	Anticipated commands after the data transmitting to the Minitab	(Action is: Update data and execute commands/Execute commands only)

Application example

Integrated system based on Minitab/DDE is proposed to design the six sigma management system for the quick changeover project of a key line in a motor manufacturing plant. Through the DDE function of Minitab accessing the production data, the process analysis can be supported to shorten the changeover time and lower the production cost.

Define Create the Minitab/DDE link (Fig. 2) to access the daily production report to collect the changeover data of each line in the first half of year 2013. Average changeover time of each line in the first half of year 2013 is as: (1) Turning, 108.2min; (2) Rotor Winding, 46.2min; (3) Stator Winding, 41.0min; (4) Rotor Assembly, 36.8min; (5) Motor Assembly, 34.4min; (6) BS shield Assembly, 25.1min; (7) Oven, 9.8min. Among them, changeover time of turning machine is the longest. So we choose the turning machine as the research object in the six sigma project.

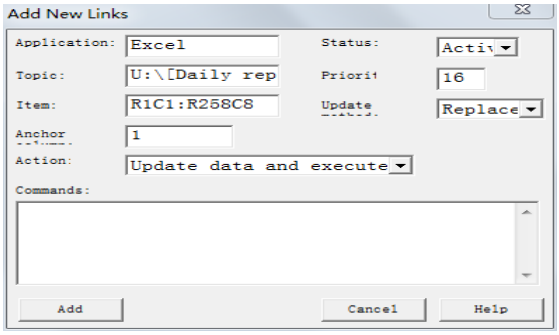

Fig. 2: DDE link of Minitab accessing the changeover data

Measure In the motor manufacturing process, turning machine is used to lathe the bearing hole in the middle and four location holes on the diagonal of AS (top) shield and BS (bottom) shield. And the usual measurement is completed by Coordinate Measuring Machine.

Select the CTQ (Critical to Quality) "Cutting depth from bearing hole to the diagonal" of AS shield as the measuring object. Let three quality checkers measure the 20 different shields twice respectively to do the Repeatability & Reproducibility analysis of gage.

According to the R&R analysis from Minitab, Coordinate Measuring Machine can be accepted.

Analyze According to the changeover process of AS shield, which is Preparation, Changeover, Checking/Debugging and Measuring, the project members analyze the possible causes from 5M1E (Man, Machine, Material, Method, Measurement, Environment) through brainstorming.

The problems mainly focus on the Changeover and Checking/Debugging:

(1) Changeover. ①The improper cooperation of two changeover workers led to the long changeover waiting and we should reallocate the actions of workers; ②It is difficult for workers to distinguish the various types of wrenches, so we take multifunctional wrench into consideration.

(2) Checking/Debugging. The Poor positioning calibration and low pass rate of "bounce from the bearing hole to the bearing turning surface" make workers to debug repeatedly and produce several pieces of scrap. To this, we may improve the craft equipment and use MAHR meter to check the locating seat of bearing hole respectively.

Improve Do the DOE (Design of Experiment) for the problems above to confirm the feasibility of the recommendations. Levels of each factor are as Table 2.

Table 2: Levels of each factor

	Lever 1	*Lever 2*
Factor A: Changeover actions	A1	A2
Factor B: Wrench	B1: Multifunctional wrench	B2:Various types of wrenches
Factor C: Craft equipment	C1: Position by MAHR meter	C2: Keep the original craft equipment

In the Table above, *A1* refers to: Dismantle and install two clamping jaws (worker X), dismantle and install one clamping jaw (worker Y), dismantle the base of UM (Y), install the base of BLDC (X), dismantle the tool rest of UM (X), install the tool rest of BLDC (X); *A2*: Dismantle and install two clamping jaws (X), dismantle the tool rest of UM (Y), install the tool rest of BLDC (X), dismantle and install one clamping jaw (worker Y), dismantle the base of UM (Y), install the base of BLDC (Y).

Besides, if the improvement of Factor C works, the problem of poor positioning can be solved and the quality of the shield also can be improved.

Create the Taguchi Design by Minitab to do the experiments. As the response variables are smaller-the-better, the SN ratios are larger-the-better and the Means are smaller-the-better. The best match is A2B1C1, that is, using the second changeover process, adding the multifunctional wrench and positioning calibration with the aid of MAHR meter.

Control The maintenance of the improvement is crucial for the project in the control stage. Not only should it standardize and document the improving process, but it also needs to build a long-term process control system to achieve continuous improvement. To this, DDE function of Minitab is more useful to realize the real-time track, identifying and guiding the secondary improvement.

Create the DDE link by adding a new link. The session command is shown as Fig. 3.

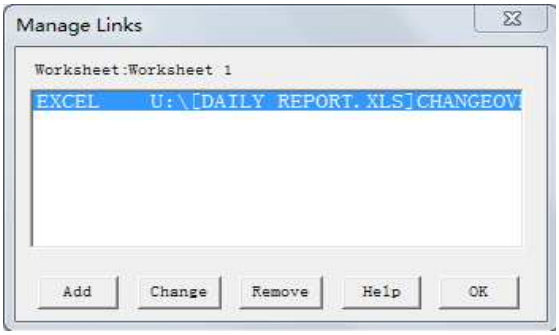

Fig. 3: DDE link command of Minitab accessing the changeover record

Access 40 changeover records in the last month and draw the Mean-Standard Deviation control chart. The points in the chart arrange randomly and are all in the limits. The mean value is 47.89min. It can be believed that changeover records are in the state of statistical control. The changeover time has reduced and stays stable. Further improvement can be achieved by the technical progress. If the points are out of limits or arrange non-randomly, abnormal causes should be analyzed. And control chart should be drawn after the improvement to determine whether the process is in control or not.

Conclusions

This paper designed the six sigma management system for the practical project based on the Minitab/DDE integrated system. This system supports the real-time interactive access to the production data to analyze the process, thus to achieve the continuous improvement of six sigma management and enhance the competitiveness of enterprises.

Keywords: Building Engineering; Specialization; Theory

Abstract. Architectural engineering, also known as building engineering, is the application of engineering principles and technology to building design and construction. Definitions of an architectural engineer may refer to an engineer in the structural, mechanical, electrical, construction or other engineering fields of building design and construction; a licensed engineering professional in parts of the United States; in informal contexts, and formally in some places, a professional synonymous with or similar to an architect. Structural engineering involves the analysis and design of physical objects (buildings, bridges, equipment supports, towers and walls). Those concentrating on buildings are responsible for the structural performance of a large part of the built environment and are, sometimes, informally referred to as "building engineers".

Introduction

Structural engineering is a field of engineering dealing with the analysis and design of structures that support or resist loads. Structural engineering is usually considered a specialty within civil engineering, but it can also be studied in its own right.

Structural engineers are most commonly involved in the design of buildings and large no building structures but they can also be involved in the design of machinery, medical equipment, vehicles or any item where structural integrity affects the item's function or safety. Structural engineers must ensure their designs satisfy given design criteria, predicated on safety (e.g. structures must not collapse without due warning) or serviceability and performance (e.g. building sway must not cause discomfort to the occupants).

Structural engineering theory is based upon physical laws and empirical knowledge of the structural performance of different materials and geometries. Structural engineering design utilizes a number of simple structural elements to build complex structural systems. Structural engineers are responsible for making creative and efficient use of funds, structural elements and materials to achieve these goals [1].

Structural Engineers

Structural engineers are responsible for engineering design and analysis. Entry-level structural engineers may design the individual structural elements of a structure, for example the beams, columns, and floors of a building. More experienced engineers may be responsible for the structural design and integrity of an entire system, such as a building.

Structural engineers often specialize in particular fields, such as bridge engineering, building engineering, pipeline engineering, industrial structures, or special mechanical structures such as vehicles, ships or aircraft [2].

Structural engineering has existed since humans first started to construct their own structures. It became a more defined and formalized profession with the emergence of the architecture profession as distinct from the engineering profession during the industrial revolution in the late 19th century. Until then, the architect and the structural engineer were usually one and the same - the master builder. Only with the development of specialized knowledge of structural theories that emerged during the 19th and early 20th centuries did the professional structural engineer come into existence.

The role of a structural engineer today involves a significant understanding of both static and dynamic loading, and the structures that are available to resist them. The complexity of modern structures often requires a great deal of creativity from the engineer in order to ensure the structures support and resist the loads they are subjected to. A structural engineer will typically have a four or five year undergraduate degree, followed by a minimum of three years of professional practice before being considered fully qualified. Structural engineers are licensed or accredited by different learned societies and regulatory bodies around the world (for example, the Institution of Structural Engineers in the UK). Depending on the degree course they have studied and/or the jurisdiction they are seeking licensure in, they may be accredited (or licensed) as just structural engineers, or as civil engineers, or as both civil and structural engineers. Another international organisation is IABSE (International Association for Bridge and Structural Engineering). The aim of that association is to exchange knowledge and to advance the practice of structural engineering worldwide in the service of the profession and society [3].

History of Structural Engineering

Structural engineering dates back to 2700 B.C.E. when the step pyramid for Pharaoh Djoser was built by Imhotep, the first engineer in history known by name. Pyramids were the most common major structures built by ancient civilizations because the structural form of a pyramid is inherently stable and can be almost infinitely scaled (as opposed to most other structural forms, which cannot be linearly increased in size in proportion to increased loads).

However, it is important to note that the structural stability of the pyramid is not primarily a result of its shape. The integrity of the pyramid is intact as long as each of the stones is able to support the weight of the stone above it. The limestone blocks were taken from a quarry near the build site. Since the compressive strength of limestone is anywhere from 30 to 250 MPa, the blocks will not fail under compression. Therefore the structural strength of the pyramid stems from the material properties of the stones from which it was built rather than the pyramid's geometry.

Throughout ancient and medieval history most architectural design and construction was carried out by artisans, such as stone masons and carpenters, rising to the role of master builder. No theory of structures existed, and understanding of how structures stood up was extremely limited, and based almost entirely on empirical evidence of 'what had worked before'. Knowledge was retained by guilds and seldom supplanted by advances. Structures were repetitive, and increases in scale were incremental.

No record exists of the first calculations of the strength of structural members or the behavior of structural material, but the profession of structural engineer only really took shape with the Industrial Revolution and the re-invention of concrete. The physical sciences underlying structural engineering began to be understood in the Renaissance and have since developed into computer-based applications pioneered in the 1970s.

Structural Failure

The history of structural engineering contains many collapses and failures. Sometimes this is due to obvious negligence, as in the case of the Pétionville school collapse, in which Rev. Fortin Augustin said that “he constructed the building all by himself, saying he didn’t need an engineer as he had good knowledge of construction” following a partial collapse of the three-story schoolhouse that sent neighbors fleeing. The final collapse killed 94 people, mostly children.

In other cases structural failures require careful study, and the results of these inquiries have resulted in improved practices and greater understanding of the science of structural engineering. Some such studies are the result of forensic engineering investigations where the original engineer seems to have done everything in accordance with the state of the profession and acceptable practice yet a failure still eventuated. A famous case of structural knowledge and practice being advanced in this manner can be found in a series of failures involving box girders which collapsed in Australia during the 1970s.

Specialization

Building Structures

Structural building engineering includes all structural engineering related to the design of buildings. It is the branch of structural engineering that is close to architecture. Structural building engineering is primarily driven by the creative manipulation of materials and forms and the underlying mathematical and scientific ideas to achieve an end which fulfills its functional requirements and is structurally safe when subjected to all the loads it could reasonably be expected to experience. This is subtly different from architectural design, which is driven by the creative manipulation of materials and forms, mass, space, volume, texture and light to achieve an end which is aesthetic, functional and often artistic.

The architect is usually the lead designer on buildings, with a structural engineer employed as a sub-consultant. The degree to which each discipline actually leads the design depends heavily on the type of structure. Many structures are structurally simple and led by architecture, such as multi-storey office buildings and housing, while other structures, such as tensile structures, shells and grid shells are heavily dependent on their form for their strength, and the engineer may have a more significant influence on the form, and hence much of the aesthetic, than the architect.

The structural design for a building must ensure that the building is able to stand up safely, able to function without excessive deflections or movements which may cause fatigue of structural elements, cracking or failure of fixtures, fittings or partitions, or discomfort for occupants. It must account for movements and forces due to temperature, creep, cracking and imposed loads. It must also ensure that the design is practically buildable within acceptable manufacturing tolerances of the materials. It must allow the architecture to work, and the building services to fit within the building and function (air conditioning, ventilation, smoke extract, electrics, lighting etc.). The structural design of a modern building can be extremely complex, and often requires a large team to complete.

Earthquake Engineering Structures

Earthquake engineering structures are those engineered to withstand earthquakes. The main objectives of earthquake engineering are to understand the interaction of structures with the shaking ground, foresee the consequences of possible earthquakes, and design and construct the structures to perform during an earthquake. Earthquake-proof structures are not necessarily extremely strong like the El Castillo pyramid at Chichen Itza shown above. In fact, many structures considered strong may in fact be stiff, which can result in poor seismic performance. One important tool of earthquake engineering is base isolation, which allows the base of a structure to move freely with the ground.

Civil Engineering Structures

The structural engineer is the lead designer on these structures, and often the sole designer. In the design of structures such as these, structural safety is of paramount importance (in the UK, designs for dams, nuclear power stations and bridges must be signed off by a chartered engineer).

Civil engineering structures are often subjected to very extreme forces, such as large variations in temperature, dynamic loads such as waves or traffic, or high pressures from water or compressed gases. They are also often constructed in corrosive environments, such as at sea, in industrial facilities or below ground.

Mechanical Structures

Principles of structural engineering are applied to variety of mechanical (moveable) structures. The design of static structures assumes they always have the same geometry (in fact, so-called static structures can move significantly, and structural engineering design must take this into account where necessary), but the design of moveable or moving structures must account for fatigue, variation in the method in which load is resisted and significant deflections of structures.

The force which is parts of a machine is subjected to can vary significantly, and can do so at a great rate. The force loaded on a boat or aircraft are subjected to vary enormously and will do so thousands of times over the structure's lifetime. The structural design must ensure that such structures are able to endure such loading for their entire design life without failing.

Aerospace Structures

Aerospace structure types include launch vehicles, (Atlas, Delta, Titan), missiles (ALCM, Harpoon), Hypersonic vehicles (Space Shuttle), military aircraft (F-16, F-18) and commercial aircraft (Boeing 777, MD-11). Aerospace structures typically consist of thin plates with stiffeners for the external surfaces, bulkheads and frames to support the shape and fasteners such as welds, rivets, screws and bolts to hold the components together.

Nanoscale Structures

A nanostructure is an object of intermediate size between molecular and microscopic (micrometer-sized) structures. In describing nanostructures it is necessary to differentiate between the numbers of dimensions on the nanoscale. Nanotextured surfaces have one dimension on the nanoscale, i.e., only the thickness of the surface of an object is between 0.1 and 100 nm. Nanotubes have two dimensions on the nanoscale, i.e., the diameter of the tube is between 0.1 and 100 nm; its length could be much greater. Finally, spherical nanoparticles have three dimensions on the nanoscale, i.e., the particle is between 0.1 and 100 nm in each spatial dimension. The terms nanoparticles and ultrafine particles (UFP) often are used synonymously although UFP can reach into the micrometer range. The term 'nanostructure' is often used when referring to magnetic technology.

Structural Engineering Theory

Structural engineering depends upon a detailed knowledge of applied mechanics, materials science and applied mathematics to understand and predict how structures support and resist self-weight and imposed loads. To apply the knowledge successfully a structural engineer generally requires detailed knowledge of relevant empirical and theoretical design codes, the techniques of structural analysis, as well as some knowledge of the corrosion resistance of the materials and structures, especially when those structures are exposed to the external environment. Since the 1990s, specialist software has become available to aid in the design of structures, with the functionality to assist in the drawing, analyzing and designing of structures with maximum precision; examples include AutoCAD, StaadPro, ETABS, Prokon, Revit Structure etc. Such software may also take into consideration environmental loads, such as from earthquakes and winds.

Keywords: PDF417, two-dimensional barcode, agricultural products, Traceability code system

Abstract. Using Visual Basic as the development platform, the agricultural products traceability code system was constructed based on the PDF417 two-dimensional bar code technology through the embedded c++ dynamic link library (DLL) in the paper. The system implemented the expression of the related information for agricultural products origin, agricultural products, certification types, agricultural products processing enterprises, production date, shelf life of agricultural products and so on. Through the effective traceability of agricultural products, the requirements of the consumers to agricultural product quality were satisfied by the system.

Introduction

Currently, the problem of food safety increasingly aroused people's concern[1]. The establishment of the agricultural products quality safety traceability system and the realization of the "from farm to table" whole process of tracking management and quality control provided the possibility of solving the problem of food safety from the sources[2-3].Applying the modern information technology in agricultural product traceability system, the efficient agricultural products traceability information platform was established using the two-dimensional bar code PDF417 bar code technology. The establishment of the complete traceability system of agricultural product quality safety in the process of agricultural production and processing could solve the problem of food safety fundamentally and further improve the quality of agricultural products in China.

PDF417 two-dimensional barcode

The development of PDF417 barcode. The PDF (Portable Data File) 417 invented by the Doctor WangYinjing was a type of layered, continuous and length variable 2 dimensional barcode. In the barcode, each symbol character is made up of four vertical bars and four spacing. If the narrowest vertical bar or spacing of barcode was called a module, the total number of the modules of the above four vertical bars and four spacing must be 17. Therefore, the barcode was called “417” code or PDF417 code. The top and bottom of the barcode were both blank area. The multilayer structure was located between the upper and lower blank area. Each layer was right and left justified and connected directly. The minimum number of the layers was 3. The largest number of layers was 90. The number of data characters in each row was same. The well-determined start character and terminate character were expressed by the 81111113 and 71111121 separately and not included in the scope of coding.

The characters of the PDF417 barcode. As a portable data files, the PDF417 barcode was widely used in logistics, manufacturing, postal service, library management, and other industries. The features of the barcode as follow:

Large capacity of information: In addition to letters, Numbers and ASCII characters, PDF417 code could also express a binary number. To make the code more compact and improve the information density, the PDF417 bar code can be used three formats in the coding: extensional alphanumeric

compressed format (can hold 1850 bytes), binary/ASCII format (can hold 1108 bytes) and digital compression format (can accommodate 2710 figures).
Strong error correction ability and confidentiality: PDF417 barcode which adopted the world's most advanced RS error correction technology could not only prevent the wrong reading and improve decoding reliability effectively, but also retrieval the missed information due to the bar code damage and pollution in a large extent.
Wide scope of coded information: PDF417 barcode could be used for coding for a variety of text, images, and biometric information such as fingerprint, palmprint and voice coding and had extensive application scope.
Easy printing and durable: PDF417 barcode was easy to manufacture and had low costing. The printing requirement of it was also not high. It could be printed on paper, CARDS and various kinds of commonly used barcode carrier employing ordinary printing devices. Moreover, the barcode should not be restricted to the number of times of read card.
The flexible methods of read: The PDF417 barcode could be identified through software after collecting data by the devices such as general camera or scanner.
Public code system: The PDF417 barcode had formed the international standard. In China, the national standard (GB/T 17172-17172) of the PDF417 barcode had formulated.

The coding design of agricultural products

The Characteristics of the agricultural product coding. To realize detailed traceability of the key information of the agricultural products, the formulating of the trace code set was the one of the most important step. To meet the constantly updated needs and practical requirements of the Chinese agricultural product traceability, the agricultural product traceability system must have the following features:
The unity of the traceability information: Unique coding was a basic principle of coding. It meant that the same objects should be assigned the same identification code and the different objects should to share the identity of the code. Once the identification code was distributed, it should try to remain the same as long as the basic characteristics of the identified object had not changed
The universality and maturity of the traceability technology: The universality generally referred to the coding can be applied and identified in the national and even global scope. The implementation of the encoding, especially for the coding used in the trade between the two parties, should adopt international standards as far as possible and follow the international standards in order to improve the commonality of the coding in the world.
The stability and maintainability of the traceability system: The condition that the code resources would not be run out in the future for a long time must be ensured. Even though the code resource was exhausted in some applications, it was must facilitate the expansion for the developers. In the case of must changing the coding, the recoding must to be realized under the condition that changed the original code as less as possible.

The composition of the agricultural products code. To achieve the traceability of the agricultural products, the agricultural products code should contain related information such as the source area, products, certification types, processing enterprises, manufacturing date, and shelf life.
The construction of agricultural products traceability code: As shown in Table 1, the agricultural products traceability code was constructed by the source area code, the processing enterprise code, the product code, the product certification type code, the manufacturing date code and the expiration date code and represented by the 31 digital code and 2 Chinese characters in this paper.
Products source area code designing: Products source area referred to the location of the agricultural planting and breeding. The source area code should be able to identify the comprehensive and detailed information of the planting plots or aquaculture area of the agricultural products. In the “encoding rules of source area of Chinese agricultural products” (the standard number: NY/T 1430-2007) which issued and implemented by the ministry of agriculture, the source area code was expressed by 20 digits. However, in this system, the source area code was designed as follow: The code for the county or higher level administrative division was expressed by the first 6 digits of the

administrative area code. The code for the street agency, town, township and village was represented by the Chinese characters.

Table 1 Construction of agricultural products traceability code

Code	*Digits*	**Chinese characters**
Products source area	6 digital codes for county or city	Geographical Names
Processing enterprises	6 digital codes for position of enterprises	Enterprise name
Products	5 digital codes	
Certification type	1 digital code	
Manufacturing date	6 digital codes	
Expiration date	6 digital codes	
Eerror correction	1 digital code	

Product processing enterprises code designing: The enterprises which process the agricultural products were identified employing product processing enterprises code. Due to the name of the enterprise which registered within the same administrative division could not be repeated, the location code of the products processing enterprises were indicated by the administrative division codes. The enterprise names were represented in Chinese characters.

Products code designing: The products code identified the agricultural products themselves based on the basic properties information of them including the types, names, varieties and so on. In this paper, the product code coded the agricultural products depending on the classes (using 1 digit), categories (using 2 digits) and product names (using 2 digits) of the agricultural products according to the basic characteristics of agricultural information. The varied and complex classes of the agricultural products referred to the primary products or processed products of various kinds of animals and plants produced by planting, breeding, aquaculture, animal husbandry, forestry and so on. According to the traditional customs, the agricultural products could be divided into seven major classes which were grain, vegetables, fruits, flowers, forest products, animal products, aquatic products and other sideline products and represented using 1 digital code. There were different corresponding categories in each class of the agricultural products. For example, according to the characteristics of agricultural biology, the vegetable class could be further divided into: cabbage, Chinese cabbage, melons, beans, edible fungus, mustard, tap root, tuber, solanaceous fruit, onion garlic, green leafy vegetables, perennial vegetables, aquatic vegetables and so on. Moreover, each category also had corresponding different genus or varieties. The genus or varieties of each category of agricultural products could be expressed as commodity name or product name. For instance, the cabbage category of the vegetable class also included cabbage, cauliflower, broccoli, turnip cabbage and so on. Therefore, during encoding the classification of agricultural products, the commodity name of the agricultural products could be used as coding object directly and uniformly and coded by 2-digital code in the agricultural product code. The 2-digital code had 99 kinds of coding set totally which was enough for further extending and reserving.

Date code designing: Date code was used to identify the production date and keeping date of the agricultural products. In the "general principles for prepackaged food labels" (GB7718-2004, mandatory national standards), the production date was clearly defined as the date of the food was processed to final product [9]. In this system, the data code was coded adopting the traditional data presentation and recorded as YYMMDD. In this 6-digital data code, YY, MM and DD expressed the year, month and date respectively. The range of MM code was 01 to 12 and denoted January to December of one year. The range of DD code was 01 to 31 and denoted each day of one mouth.

Certification type code designing: At present, the agricultural product certification types in China mainly included 3 types: the pollution-free agricultural products certification, the green agricultural product certification and the organic agricultural products certification. The other types of the

agricultural products certification which was not included in above three types could be classified as "other agricultural product certification" and represented using 1 digital code.

System implementation

The design of agricultural products traceability code system. Employing the VB as development platform, the system was established through embedded Access database and VC DLL. The flow chart of the system was shown as Figure 1:

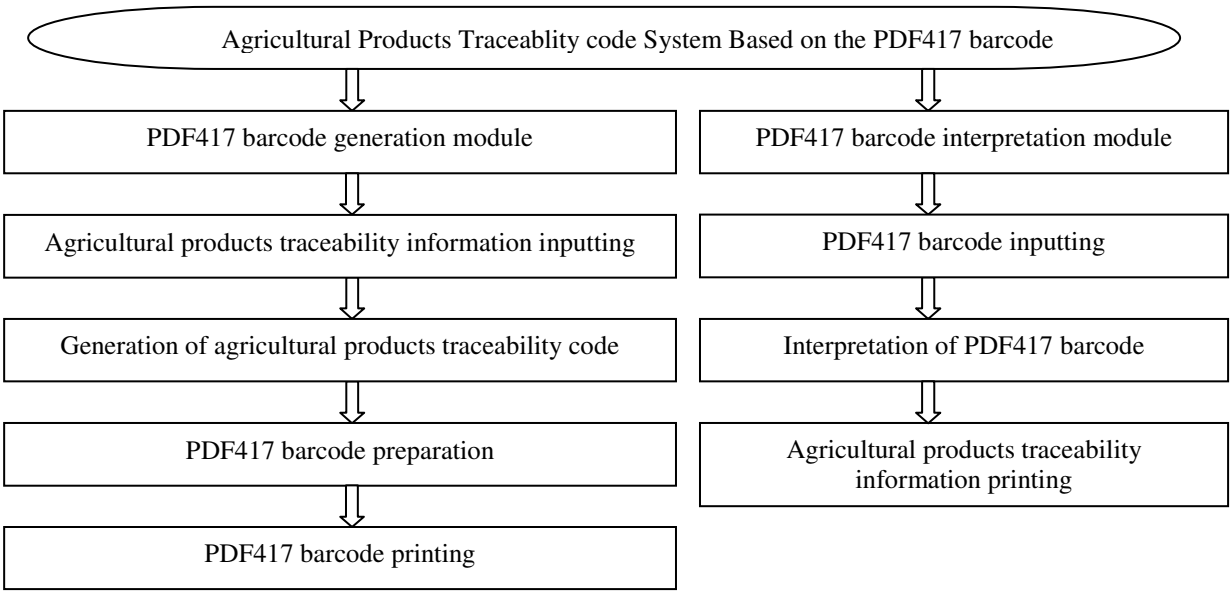

Figure 1 The flow chart of system structure

Database design: Using Access, the related database of the agricultural products traceablity code system was established. The database which consisted of the products source area code table, products code table, certification type code table, administrative district and division code table was implemented to code the agricultural products data. Under the environment of VC, the PDF417 encoding and decoding application programs were written based on PDF417 two-dimensional barcode coding principle and the coding scheme of the agricultural products traceability code described in this paper. After that, the dynamic link library (DLL) also was generated to encode the organized coding information of the agricultural products to the PDF417 barcode.

Agricultural products information inputting: The information of agricultural products such as source area, manufacturing enterprise location, enterprise name, types of product certification, product category, product name, production date and expiration date was entered in the textbox of the main interface of the system. At the same time, this information of agricultural products was produced into a text file and stored in the current folder. The text file would be loaded in the text box of the main interface of the system during the system operating.

Agricultural products code generation: Click on the code generation button on the main interface, the system would classify the data on the basis of the agricultural products information in the textbox and further form a code generation interface. On the interface, the agricultural products information could be altered. After confirmation, press the save button, the agricultural products information code would be generated.

PDF417 barcode generation: Press the barcode generation button, the PDF417 barcode of the agricultural products would be generated call the coding program of dynamic link library (DLL) and displayed in the picture box of the system main interface.

Barcode analysis: Press the graphics file button on the main interface, the PDF417 barcode image saved as the bitmap (BMP) file would be imported in the picture box of the system main interface. Press the barcode analysis button next, the system would call the decoding program of the dynamic link library (DLL) and resolve the PDF417 barcode. The analytical would be shown in the text box at top right-hand corner of the system main interface.

Summary

The agricultural products traceablity code system based on the PDF417 barcode was constructed in this paper. The system standardized the coding and decoding process of the PDF417 barcode of the agricultural products. The operation interface of the system was simple and easy to use. At the same time of satisfying the general requirements of enterprises, the system also considered of the features of the corresponding enterprise and would be widely used and popularized.

Research on Designing the Information Management Platform of Physical Education based on B/S Model

Guoying Wang

Sports Department, Henan University of TCM, Zhengzhou, 450008, China

Keywords: B/S framework; VB programming; PE; Management platform; Communication port; Editor; LED display

Abstract: This paper, by using multi-layer B/S framework model, combines with VB programming to carry out innovative design of physical education (PE) platform, which has got the B/S framework platform of PE management. PE information management platform mainly comprises the teacher end, the central processor unit (CPU) and the student end, where the communication interface mainly comprises the editor and the computer, and the input of teacher end includes the computer buttons, sensors, and so on. While for the core parts of the system, they are the CPU and the memory demonstrated by PE. Student end through the I/O expansion function analyzes and displays the teaching sound and video signal displayed by using LED or LCD. Finally, the paper designs the data analysis and transfer function of PE information platform, and obtains the curve of information throughput with time changing, which provides a new computer method for the research of PE.

Introduction

The principle of B/S framework-based data mining algorithm is mainly with the membership function to search for the correlation of data[1,2]. In the design of PE information platform, the management and analysis of student performance data is one of the most important parts to be designed. Using the data mining theory can realize the layering and sorting of data. For the sorted data, it can use B/S framework model to make information statistics, then it can eventually obtain the correlation between local data and the overall data, so as to provide theoretical guidance for the PE [3,4]. It can use the membership function to analyze student performance data, where the expression form of the membership function is as shown in formula (1).

$$P(y)=\frac{y-m}{M-m}. \tag{1}$$

Where M denotes the maximum value of student performance, and m denotes the minimum value of student performance. The calculation expressions of the output performance data processing are as shown in formula (2).

$$\begin{aligned} x_{m,\frac{n}{2}} &= \sum_{i=-M+n}^{n} b_{i-n}, d_{m+1,i} \\ y_{m,\frac{n}{2}} &= \sum_{i=-M+n}^{n} u_{i-n}, d_{m+1,i} \end{aligned}. \tag{2}$$

The sorting formula of student performance can be expressed as the formula (3).

$$f_{o,p}{}^{(n)} = f_{o,p}{}^{(n-1)} - [\sum_{o} u_{o,p+1}{}^{(n)} G_p{}^{(n)} + \frac{1}{2}]. \tag{3}$$

Where G_p denotes the sorting coefficient of B/S framework-based data algorithm, it can eventually obtain student performance of multi-level B/S framework-based data structure model, and the equation is as shown in formula (4).

$$\begin{array}{l} G_{p1}^{\ i} \quad \ldots \quad G_{p}^{\ i}{}_{n/2i} \\ \quad \ldots \\ G_{p1}^{\ 2} \quad \ldots \quad \ldots \quad G_{p}^{\ 2}{}_{n/2i} \\ G_{p1}^{\ 2} \quad G_{p2}^{\ 2} \quad \ldots\ldots\ldots \quad G_{pn}^{\ 1} \\ \Rightarrow \quad \Rightarrow \quad \Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow . \\ S1 \quad S2 \quad \ldots\ldots \quad \ldots \quad \ldots\ldots \quad \ldots\ldots \quad S_n \end{array} \tag{4}$$

Where S denotes the level and the number of calculation of the algorithm. The student performance is carried out the data analysis by using VB program in this paper, and the used main program algorithm is shown as follows.

```
#include <stdio.h>
void main()
{float x,y(float c),a,b;
  a=-10;
  b=10;
  do
  {x=(a+b)/2;
       if (y(a)*y(x)<1e-10) b=x;
       else a=x;}
  while (a-b>0.00001);
  printf("x=%f,\n\n",x);}
float y(float c)
{float z;
  z=2*c*c*c-4*c*c+3*c-6;
  return(z);}
```

Application Research of Computer in the Design of PE Management Platform

In order to verify the validity and reliability of the mathematical model and the algorithm for performance management designed in the second part in this paper. The algorithm is debugged by using VB programming software, and it finally obtains the applicability of the B/S framework model by using the correlation of multiple groups of user's mode debugging data[5,6].

Fig. 2 Design of student user management

As shown in Figure 2, the student ID without blank lines in the student course selecting list is saved, and the saved path is on the "username" that is in the "imp_stutolesson_demo" file [7]. It can quickly upload student course list by using the function, finally, the course list of Excel file can be imported to the corresponding network teaching course.

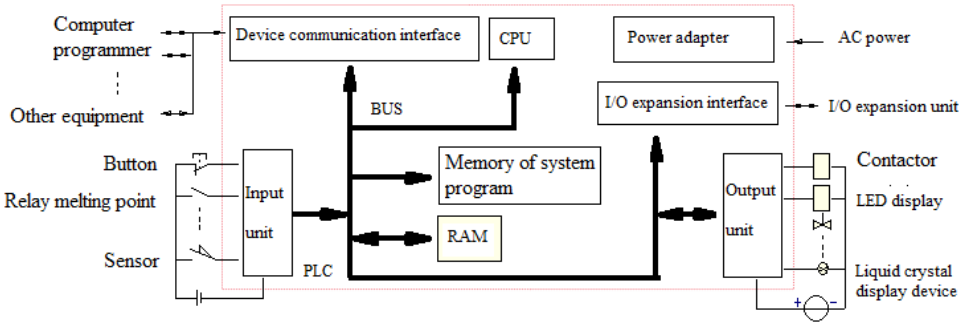

Fig. 3 Schematic diagram of computer and circuit port

Figure 3 shows the schematic diagram of computer and data interface of circuit. The communication interface mainly comprises the editor and computer. The input unit includes computer buttons, sensors, and so on. The core parts of the system include the central processing unit and the memory demonstrated by PE [8]. With the expansion function of I/O, teaching management information platform transmits the teaching sound and video signals through the device, and after the signals are delivered to the student end, that are displayed by using LED or LCD.

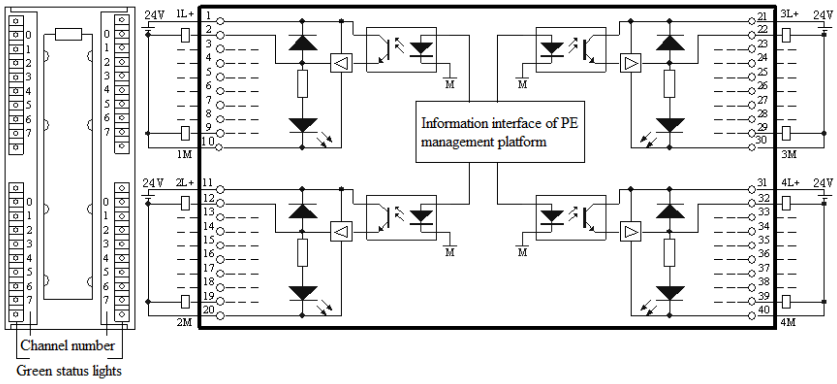

Fig. 4 The internal circuit and external terminal wiring diagram of the output module from digital transistors

Figure 4 shows the internal circuit and external terminal wiring form of the output module from digital transistors. With the use of this circuit connection, it can realize processing of mass data, at the same time, teacher end can realize teaching information upload, and student end can realize the save function of student information.

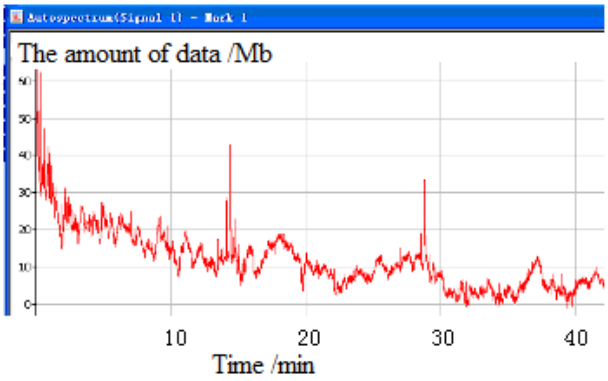

Fig. 5 The process of data transmission

Figure 5 shows the process of data transmission. It can be seen from the chart, the amount of data transmission is obviously different at different time, which shows that the used function and the number of users are different at different times, when the users use the teaching information management platform [9]. It can be seen from Figure 5 that the system function is in normal operation, and there is no amount of data overflow or negative.

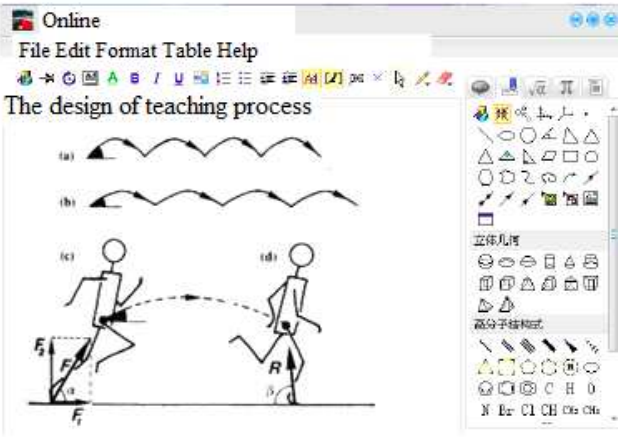

Fig. 6 Visual function of teaching system interface

As shown in Figure 6, visual function of teaching interface mainly includes the drawing, data transmission and redrawing . In the process of image drawing, the user can draw graphs of various forms by using the brush function, and the image can be presented to students in real time by using the information transmitting device.

Table 1. Association membership table

Performance level	Range	Value
Fail	Min-B1	B1
Good	B1-B4	B2
		B3
		B4
Excellent	B3-max	B4

Table 1 shows the association membership table of student performance designed by using PE information management platform. With the use of B/S framework model, it can make classification statistics on student performance, and with the correlation function, it can study the correlation of student performance data, so as to find the influence of student partial performance on the overall performance, which can provide a theoretical reference for the PE process.

Conclusion

This paper established B/S framework mathematical model of data mining algorithm and combined with VB programming algorithm to carry on the design of PE information platform. Finally, it obtained a new sorting method of PE performance, and the algorithm realized the correlation analysis of student performance. The teacher end, the central processor and the student end of PE information management platform were respectively designed, and the function of platform was design by using the central processing unit, the memory and I/O expansion functions. Based on these, it obtained multifunctional PE management platform. The paper carried out the design of correlation for teaching performance by using PE information management platform, which had provided technical support for the research of PE.

Study on the Construction of Linguistics Examination Database based on Computer Network Technology

Yuan Zhang

School of Foreign Languages, Jiangsu University of Science and Technology, Zhenjiang, 212003, China

Keywords: VB software; English linguistics; Network examination database; Feedback system; Distortion; Network teaching

Abstract. In this paper we use the VB software to programming the group program of tests, combined with neural network residual training principle, establish optimization design model of network examination database. We improve the English linguistics question bank based on computer network technology by using the program and the model, and set up the feedback system of students' suggestion and Corporate Data Stores system of examination paper, and establish optimization model of network examination database. In order to verify effectiveness and reliability of network test optimization system, we optimize the network examination database of English Linguistics for three times, obtain the optimal distortion curve of test, and analyze optimized test scale. It provides technical support for the research of network English teaching.

Introduction

In recent years, with the extension of network application, the computer is getting close with educational fields. Paperless electronic paper is a new method to deepen the reform of education and promote innovation teaching. The computer network examination database greatly improves the efficiency of examination, saving a lot of teaching resources, but the construction of network examination database is still at primary stage, many problems still remain to be perfect [1, 2]. Combined with the neural network residual training method, we use the VB software technology to design the optimization system of computer network technology English examination database, and use three optimizations to optimize the network examination database. It provides a new method for application of computer in English teaching and network education.

Application of Computer Network Technology in the Construction of English Examination database

With the development of Internet and information technology, network examination database is widely used in English teaching. The question bank not only can save a lot of resources, but also make the teachers and students to make full use of network source, improving efficiency of teaching and learning, enhance the students' self-study ability [3, 4]. In this paper, we use the VB software to optimize the design of English network examination database, and apply the computer in the English linguistics examination. The design process of examination database is as shown in Figure 1.

Figure 1 shows the network examination database optimization flow chart of English linguistics. From it we can see, by VB software it can realize several optimizations of English network examination database, and the optimization is t tree distribution [5]. After one optimization we can get $ST1, ST2, \cdots, STn$; after two optimizations we can get $ST11, ST12, \cdots, ST1n$; after n optimizations we can get the optimal model of examination database, the convergence residual of examination database is the lowest, distortion of test is lowest, and the effect of network test is the best.

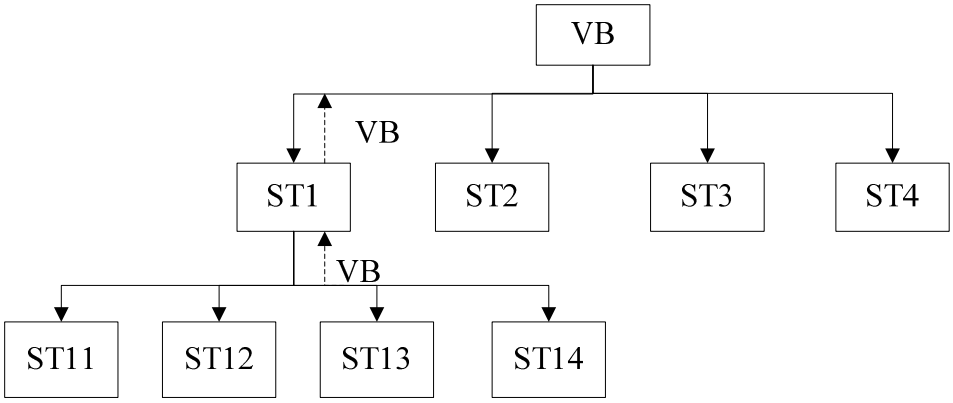

Fig. 1 Network examination database optimization process

The Mathematical Model and Algorithm Design of English Linguistics Examination database

In order to optimize the English linguistics examination database and accelerate the convergence speed, we improve the calculation model using the first order difference quotient. First defining the parameters of initialization examination database x_0, after modifying parameter of examination database is x_1 [6, 7]. So, one order difference quotient can be written as shown in formula (1).

$$P(x_0, x_1) = \frac{P(x_1) - P(x_0)}{x_1 - x_0}. \tag{1}$$

The two order training difference quotient is defined as:

$$P(x_0, x_1, x_2) = \frac{P(x_0, x_2) - P(x_0, x_1)}{x_2 - x_1}. \tag{2}$$

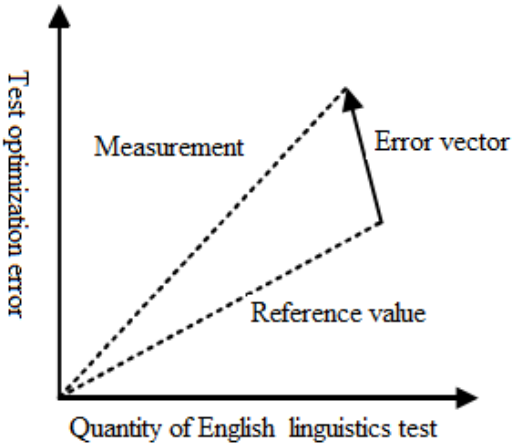

Fig. 2 Optimization model of English linguistics test

As shown in Figure 2 it represents optimization model of English linguistics test. According to the reference quantity and test quantity, we can do two order difference quotients training on English linguistics examination database [8]. The deviation table in computer is as shown in formula (3).

$$\begin{cases} F_{i0} \Leftarrow P(x_i) \quad , \qquad i = 0,1,...,n \\ F_{ij} \Leftarrow (F_{ij-1} - F_{i-1\,j-1})/(x_i - x_{i-j}), \quad j = 1,2,...,n. \quad i = j, j+1,...,n \end{cases}. \tag{3}$$

According to the definition of difference quotient, data x can be seen the point between $[a,b]$ in English linguistics examination database, so we can get:

$$P(x_0,x) = P(x_0,x_1) + P(x_0,x_1,x)(x-x_1),$$
$$\cdots$$
$$P(x) = P(x_0) + P(x_0,x\ )(x-x_0) \quad . \tag{4}$$
$$P(x_0,\ldots x_{n-1},x) = P(x_0,x_1,\ldots,x_n) + P(x_0,\ldots,x_n,x)(x-x_n)$$

Based on the neural network model of English linguistics examination database, we use the VB software to design the examination database. The main program of VB is as shown follows:

```
#include <stdio.h>
void main()
{void average(float *p,int n);
    void search(float (*p)[4],int n);
    float score[3][4]={{65,67,70,60},{80,87,90,81},{90,99,100,98}};
    average(*score,12);
    search(score,2);}
void average(float *p,int n)
{float *p_end;
    float sum=0,aver;
    p_end=p+n-1;
    for (;p<=p_end;p++)
        sum=sum+(*p);
    aver=sum/n;
    printf("average=%5.2f\n",aver);}
oid search(float (*p)[4],int n)
{int i;
    printf("the score of NO.%d are:\n",n);
    for (i=0;i<4;i++)
        printf("%5.2f",*(*(p+n)+i));}
```

Research on Examination Database Design of English Linguistics based on Computer Network

In order to verify the effectiveness and reliability of the English linguistics network examination database optimization model and VB program, we use the design of network linguistics examination database as an example to analyze the optimization effect of network examination database [9]. Before the examination database optimization we need to set the variable environment of ActiveX control, as shown in Figure 3.

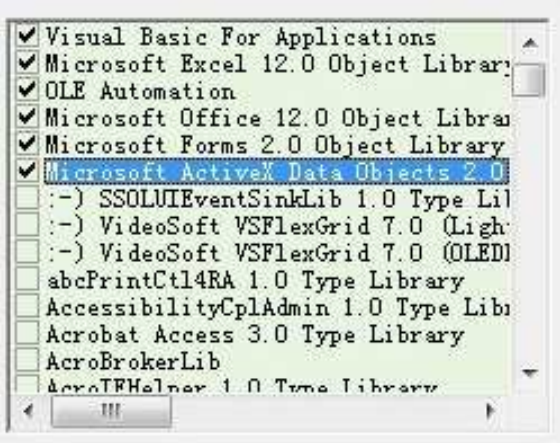

Fig. 3 Variable settings of ActiveX control

As shown in Figure 3 it represents variable setting of ActiveX control. Using Microsoft ActiveX Data Objects2.0, we design the space variable environment, and connect it with Web Server, and establish the optimization platform of English linguistics examination database as shown in Figure 4.

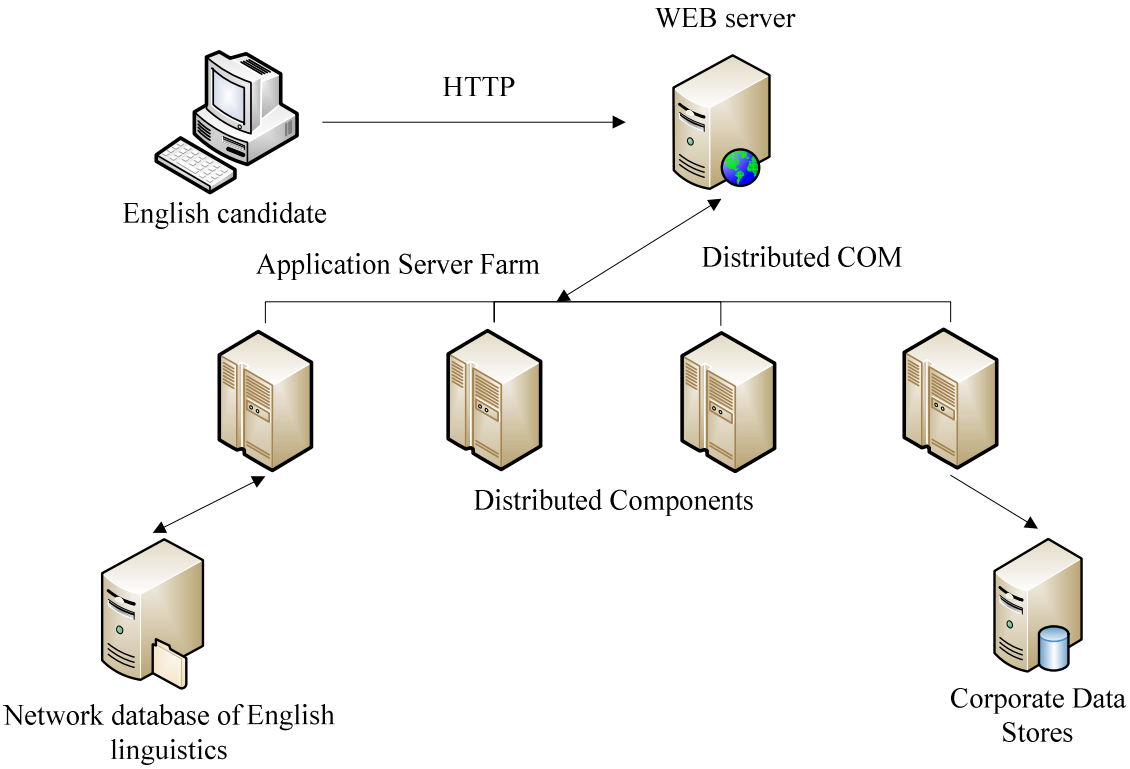

Fig. 4 Network examination database optimization platform of English linguistics

Figure 4 shows the Network examination database optimization platform of English linguistics designed in this paper. Students can use the platform to select questions and finish the test paper. Test paper distribution uses distributed allocations of Web Server and Disrtibuted COM, and uses different Disrtibuted Components to optimize the test papers [10]. Students can also feedback the examination information timely, and use Corporate Data Stores to collect data, finally forming network examination database of English linguistics.

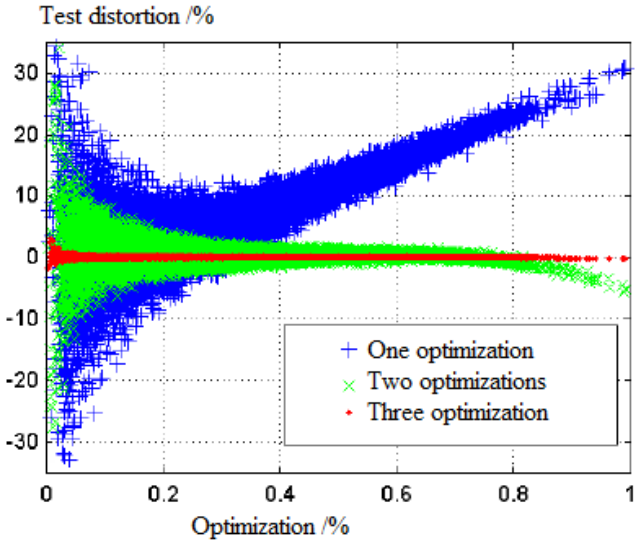

Fig. 5 Three optimizations of English network examination database

Figure 5 shows the three optimizations of English network examination database using VB program. The abscissa represents the optimal percentage, the ordinate represents distortion rate of test. From the figure we can see, distortion rate of one optimization and two optimizations is significantly larger than three optimizations. After three optimizations the distortion rate is close to *0*, which achieves the optimization effect of network examination database. We list the test quantity of three optimizations as shown in Table 1.

Table 1. Three optimizations results of English network examination database

Project	One optimization	Two optimizations	Three optimizations
Listening	201213	198651	185672
Speaking	101325	98256	88926
Reading	8592	7986	6931
Writing	7983	6526	5308

Table 1 shows the three optimizations results of English network examination database using VB [11]. In order to verify the effectiveness of the system, we use the method of three optimizations to optimize the listening, speaking, reading and writing in English examination database, and finally get the quantity of the optimized test.

Summary

In this paper we use the principle of neural network two order difference quotients training to establish optimization mathematic model of network examination database, and use VB software to program the algorithm to obtain the paper packet program. We use VB software and Microsoft ActiveX Data Objects2.0 to design optimization platform of network examination database, and introduce the paper feedback system and the Corporate Data Stores system on the platform, and perfect the optimization function of network examination database. In order to verify effectiveness and reliability of network test optimization system, we optimize the network examination database of English Linguistics for three times, obtain the optimal distortion curve of test and the quantity of optimization examination database. It provides technical support for the research of network English teaching

Keywords: Groundwater; J2EE; management information system.

Abstract. The design of groundwater management information system: using Struts Spring and Hibernate framework for system design and application development, according to the three layer design of J2EE，the key technology of every layer of the groundwater management information system was designed. The system functions include the basic data maintenance, data analysis, modeling and integrated management. The system provides management personnel with system level support in the analysis of historical data, daily monitoring and groundwater utilization.

Introduction

With the rapid development of Internet, it is becoming the mainstream of management information system basing on the browser to access WEB. J2EE architecture is suitable for application characteristics and the trend of Internet. The architecture provides standard model for the development and deployment of enterprise applications. The J2EE is adopt for the design thought which is the different layers of components .It makes business logic independent of the traditional client and the server. It is adapted to the changing needs of the business and the complex logic .It is convenience for the development, maintenance and use of the system [1]. Groundwater management information system is based on J2EE architecture to design and develop. The information system, according to the principle of high cohesion and low coupling, has the characteristics of scalable, cross-platform, easy maintenance. It provides a convenient, reliable and efficient information service about groundwater for staff, managers and decision makers.

System architecture design

J2EE is a multi-layer architecture based on component and application service [2].It is the technology architecture for the WEB system development. It is divided into the presentation layer (UI), business logic layer (BLL), and data access layer (DAL) from the business application level. It is the standard platform for the enterprise to provide a platform independent, portable, multi-user, safety and to simplify development, management, and deployment for the application system. The architecture design of groundwater management information system based on J2EE layered is shown in Fig.1.

SYSTEM FUNCTION FRAME

The function of groundwater management information system mainly includes basic data maintenance, data analysis, modeling information analysis, comprehensive management, and interacting with the GMS modeling platform for data. This system offers a variety of charts of the groundwater data analysis .These charts include histogram, pie charts, trend charts, radar map, geographic information as well as the output image from GMS modeling.

In the rights management aspect, this system designs multi-layer rights such as researchers, roles, functions and data access and so on. The rules are according to the different personnel distribution of different roles, and according to the different role assignment of open function permission and data

permission. The system could provide Announcement, industry news and simple OA office functions. The frame diagram frame of the system is shown in Fig.2.

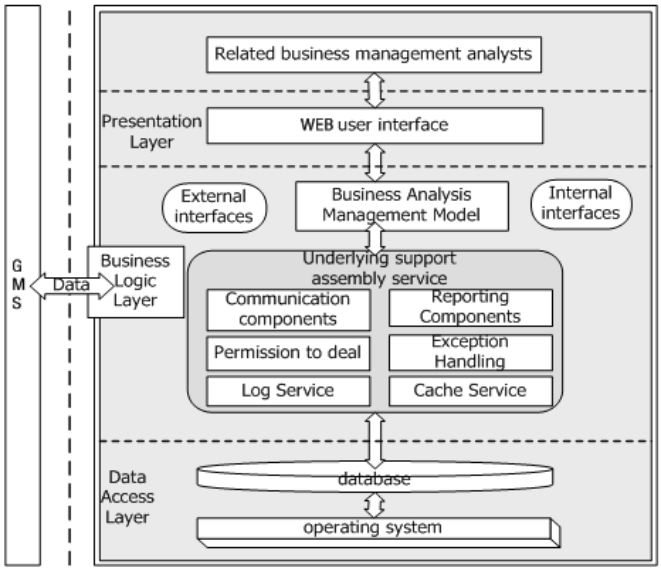

Fig.1: The architecture design of groundwater management information system

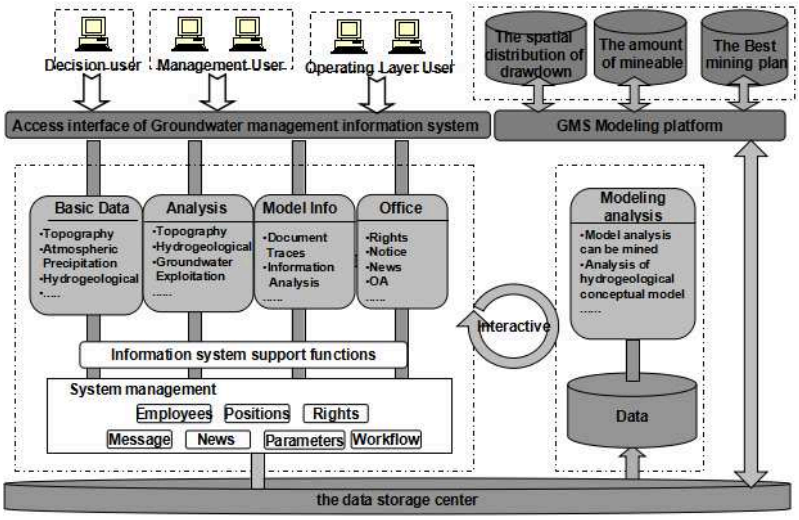

Fig.2: The frame diagram frame of the system

Maintenance functions to basic data. The maintenance function of basic data is the basis of groundwater management system function. Groundwater basic information is given preferentially with the batch information import, and other system interface is complementary. artificial acquisition entry for supplementary manner. This manner is as far as possible to reduce artificial workload, and to improve the accuracy and timeliness of information input.

Data analysis and modeling information analysis function. The function of data analysis and modeling information analysis is the core of the groundwater management system. This part is made logic operations and analysis of data and batch calculation of database through the study of basic data and GMS modeling results. This part gives various indicators of groundwater by means of statistical analysis, trend analysis and forecasting analysis. The purpose is to provide technical support and assurance for groundwater management system.

Comprehensive management function Comprehensive management function is the auxiliary function of groundwater management system. This feature can promote system security, convenience and industry development.it is the necessary basic function to the daily office.

System design and development

Performance layer----the Struts framework Struts is widely used in the JSP Web application field. This technique is an application framework which is based on the MVC (Model View Controller) pattern. The Struts controller component is integrated to achieve the model and the view [3]. The level of the Struts framework structure is clear, high reusability. The characteristic of struts enhances the scalability of system development, and provides a method of central treatment for a single page verification, access control and log processing, internationalization and so on.

Relevant jar package of the Struts is put under the WEB_INF file, at the same time, and introduced in the web.xml. The introducing corresponding configuration content is as follows:

The core part of the Struts is Action Servlet which is a part of controller. When JSP page submits request, the Action Servlet controls the traffic flow and jumps page through the configuration file struts-xx-config. This configuration file is defined on the web.xml at the same time.

Business logic layer----the Spring framework Spring is a lightweight framework of container .It could realize control inversion and aspect oriented programming, so that to solve the complexity and redundancy of enterprise application development .This technique provides a consistent management business object method. By means to control inversion, it achieves loose coupling between the system modules. Spring also provides the only access to data abstraction, including JDBC framework which is simple and efficient. This way greatly improves the efficiency and reduces the possible errors. Spring provides support for the framework of Struts and Hibernate [4], it is in favor of integration of other excellent open source framework as well.

Groundwater management information system uses the Injection method of setter and getter which exists in the Spring framework. It is made a following statement in the corresponding configuration file --applicationContext-xx.xml.

Data access layer-----Hibernate framework Hibernate framework is used in the data access layer. It is easy to use and efficient greatly which is based on O-R-Mapping (object-relational Mapping) framework. It improves the convenience and performance of database operations. Hibernate makes lightweight object encapsulation for JDBC (Java database connectivity).It may manipulate the database by way of object-oriented programming. It encapsulates database operations and shields code difference from different system .That systems are produced by the different database products (such as Oracle, Sybase, SqlServer etc).The advantage of Hibernate is improving the applicability and extensibility of the data access layer code.

Groundwater management information system integrates Hibernate framework by the Spring framework. The configuration file is in application-context.xml.

GMS modeling results output Groundwater numerical simulation model is an important tool for evaluation and management of groundwater resources. The hydrogeological conceptual model of the numerical simulation is established by using the GMS （Groundwater Modeling System）. GMS is a comprehensive groundwater numerical simulation software including model pre-processing, the numerical calculation and model after-processing [5].Groundwater management information system obtains the data analysis of GMS software and the corresponding multi-dimensional graphic data through Interface and stores these into the system. These files are maintained and associated binding information through the management interface. Other people can see the intuitive modeling and analysis results through system.

Charts and data analysis Data analysis charts are showed by the HighCharts plug-in. HighCharts is the chart written in pure JavaScript library. Its interface is aesthetics. It could be interactive charts. The realization of HighCharts does not need to use any client plug-in, and also does not need server in the background generated in advance [6]. It can take a variety of different types of charts such as histogram, trend chart to integrate a multi-dimensional analysis shows in the same chart. This system imports related highcharts.js, exporting.js into HighCharts. The data obtained is displayed in figures.

Conclusions

Groundwater management information system was designed based on J2EE architecture combined with the GMS groundwater modeling software, the system provides function s including information sorting, analysis, calculation and integration, and improves the groundwater historical information data usage and utilization. The system provides groundwater researchers and managers with the data analysis, modeling information analysis function and a good basis for scientific management of groundwater. Through the construction of groundwater information management system, unified management，planning and analysis are promoted.

Keywords: multimodal teaching; English; cloud computing

Abstract: With the rapid development of computers and the Internet, information technology has brought about great changes to our educational field. At present the ubiquitous "cloud service" has brought education into "the cloud era". Cloud computing has found more applications in our English teaching. Integrating the technology of "cloud computing" with the theory of "multimodal discourse analysis", this paper researches how to carry out multimodal English teaching in the cloud computing environment.

I. Introduction

The 21st century is an information age. Now information technology has been widely used in our educational field. The ubiquitous "cloud service" has brought education into the "cloud era". In our college English teaching, by integrating the technology of "cloud computing" with the theory of "multimodal discourse analysis", we can establish the new multimodal English teaching mode based on cloud computing, which can construct the open learning platform and implement "individualized" teaching program so as to foster more new practical talent for our country.

II. The Necessity of Multimodal English Teaching in Information Age

With the wide application of digital, network and multimedia technologies, multimodal communication has become an important part of social communication. On the basis of such a social background, the research of multimodal theory came into being. "Multimode" generally refers to the five communicative modes: casual mode, auditory mode, tactile modality, olfactory modality and taste mode, which come from the five perceptual channels. Visual mode and auditory modality are most closely linked with foreign language teaching.

The British scholar Halide once pointed out "language is a social symbol"[1]. Language is to express meaning. The famous Chinese scholar Zhuanglin Hu also pointed out "all kinds of modes have the potential to express meanings"[2]. Another British scholar Kress thought "Halide's theory of social semiotics promoted the research of multimodal expressions"[3].

Education is a key on which the multimodal research focuses. The modern foreign language teaching is an activity in which teachers and students interact and communicate with each other by means of many kinds of media. We think that the English teaching mode can be chosen from the following three angles: 1.Providing teaching situations and convenient conditions for English teaching so as to improve teaching efficiency. 2. Providing auxiliary conditions for English teaching so as to improve teaching efficiency. 3. Providing multichannel expressions of discourse for multimodal communication of discourse [4]. In addition, we should pay attention to the training of "multiliteracy ability" when we entered the new century. Our era has changed from the era of "pen and paper" to the "information era". "Multiliteracy ability" denotes that one can read all the educational and modal information that he can get in touch with [5]. We think that developing students' "multiliteracy ability" should be carried out in the following ways:

A. Classroom Teaching

Classroom teaching is a process of multimodal discourse, which involves teacher's speech and actions, the interaction between teachers and students, PPT demonstrations, the words and pictures of the textbook, interactive whiteboard, audio frequency and visual frequency, etc. Sometimes one

mode depends on the other modes to finish passing information, for example, pictures must be accompanied with oral explanations and PPT courseware must be accompanied with teacher's verbal explanations and body language. In addition, classroom teaching resources should also be multimodal. PPT courseware should include cartoons, audio frequency, visual frequency and other meaningful expressions. The teachers should flexibly use multimodal materials to present teaching contents in the network environment.

B. Extracurricular Autonomous Learning

In information age, college students' extracurricular learning is based on the network, which differs greatly from the traditional extracurricular learning. The network environment supported by cloud computing will further promote the multimodal learning, for example, teachers can put a lot of multimodal learning materials on the "cloud". Students can search the Internet for the needed materials, finish the learning tasks online, submit their homework and communicate with their teachers. Online reading and writing provide multimodal requirements for designers, guiders and learners. The dynamic nature and hyper connectivity of online reading and writing demand learners to possess cognitive flexibility of crossing disciplines, modes, languages and cultures. In this sense, carrying out "multimodal teaching" is not only an inspiration but also a great challenge. In the multimodal environment, teachers should first possess strong "multiliteracy", then they can gradually guide students to develop the corresponding ability.

C. The Research of Teaching Materials

The teaching material is the basic element of the English teaching, the main base of teachers' teaching and the central content of students learning. In order to adapt to the needs of advanced information technology and students' multimodal learning, compiling multimodal English teaching materials has become an important task. Multimodal English teaching materials refer to the English teaching materials which are formed by multimode, including written language, pictures, forms recording and videotapes, in which written language plays an important role, but many modes vie for attention [5]. Multimodal English teaching materials include paper teaching materials, electronic teaching materials and demonstrative teaching materials. Cooperation, multidimension, network and intelligence characterize the teaching materials. But there was little such research at home and abroad in the past.

Guided by the theories of multimode and the language teaching in the cloud computing environment, we can use the experience of compiling the corresponding teaching materials for reference to further study how to compile multimodal English teaching materials.

III. The Multimodal English Teaching in the Cloud Computing Environment.

We think that the multimodal English teaching in the cloud computing environment should include the following contents:

A. Developing the Multimodal English Teaching Resources in the Cloud Computing Environment

One of the basic elements of carrying out multimodal English teaching is multimodal teaching resources which are very important for both teachers' teaching activities and students' extracurricular autonomous learning activities. The central content of developing teaching resources is the construction of multimodal corpus. In addition, it includes compiling teaching materials with excellent pictures and texts, hypertext PPT courseware and network teaching materials, etc. We should extensively collect multimodal oral and written English materials by means of all kinds of modern information means, classify them according to their uses and modes such as text, recording, visual frequency, etc. We should do a good job of numbering and keyword search, gradually set up the multimodal corpus and constantly perfect it in the teaching practice so as to make it effectively serve classroom teaching and extracurricular autonomous learning in the cloud computing environment.

B. The Design of Multimodal English Classroom Teaching Supported by Cloud Service

Cloud service includes the service of network cooperative platform provided by network operator and the service of interpersonal communicative platform which people often get in touch with in their daily life. Classroom design includes teaching objectives, teaching contents, modal transfers, teaching methods and steps, etc. The theoretical guidance of the design is the theory of multimodal discourse analysis. We should utilize the advanced technology of multimodal discourse analysis such as the cooperative cloud computing platform and text visualization software to analyze the schematic structure of the text and language features, select the suitable materials from the cloud service platform and integrate all kinds of multimodal teaching resources so as to make students efficiently master the corresponding English knowledge and quickly improve their English level.

C. The Establishment of the Multimodal English Network Learning Environment Based on Cloud Computing

First, we should put all kinds of multimodal learning resources on the cloud. The search engine of the cloud should be connected with corpus and electronic teaching materials. We should present FAQ, the search of keywords, the analysis of the language points and the themes of the texts in the website. In addition, we should create blogs, micro messages and real-time dialogue programs to let teachers and students communicate with each other after class, and establish the platforms of teaching plans and homework displays. By means of different ways, the students can comprehensively experience the advantages of network learning in the cloud environment, which can fully demonstrate the effective supplement of extracurricular learning for classroom teaching. Based on the university's website and sound laboratories, we can set up a language learning laboratory of cloud computing. In class, we can extract materials from the public server to coordinate teaching. After class, students can log on to the network platform to review the materials learned in class and download more learning materials.

In the multimodal English teaching based on cloud computing, classroom teaching must be combined with the extracurricular autonomous learning. They must supplement each other to cooperatively improve students' English level.

IV. Summary

The multimodal English teaching in the cloud computing environment integrates cloud computing with multimodal English teaching. The combination of the information technology with the advanced educational theory facilitates teachers' teaching and students' learning in the information age. This innovative English teaching mode also provides a new research perspective for us English teachers. We should make good use of the new teaching mode and try hard to improve our English teaching level so as to train more useful talent for our country and society.

Keywords: middle size enterprise; cloud computing; public service platform;

Abstract. Based on the research in cross-regional resource scheduling and massive data storage, the article built public service platform including IaaS, PaaS and SaaS. It provided all kinds of management software and business software for middle size enterprise users, and provided the development, testing, deployment platform for software vendors, and provided unified resource management, monitoring and maintenance for platform operators which finally become cloud service platform to support enterprise management and software development lifecycle. This helps to form a self-loop and self-development cloud computing ecosystem, to form the linkage of cloud services production, cloud services consumption and cloud service management, and to provide comprehensive information support for the growth and development of middle size enterprise.

Introduction

Middle size enterprise is important component in the development of our national economy, which plays an important role in the expansion of the total economy, alleviating employment pressure, promoting technological innovation and maintaining the social stability. With the progress of economic globalization, middle size enterprises pay more attention to the use of information technology to improve enterprise profitability and competitiveness. But due to their small scale and low capital investment, middle size enterprises invest little in Informatization. These formed the following contradiction. The demand for IT resources is increasing year by year, the demand for various kinds of software is increasing day by day, the demand for rapid construction of information system and service portal is growing [2]. The emergence of cloud computing provides a new way to solve the difficult information problem, its technical characteristics and business model has to promote and support function that can improve the management level, production efficiency and market competitiveness. Firstly, enterprise user can use high-quality service and don't need to invest a lot of money, which can relieve the pressure on funds shortage and reduce the risk of system implementation. Secondly, software vendors can reduce operating investment and maintenance costs, and gain huge business opportunities. Finally, platform operators can realize unified management, unified control and unified backup etc.

Foreign cloud computing platform is relatively mature. Amazon's Elastic Compute Cloud (EC2) and simple storage service (S3), dedicate to the task of calculating and storing process for small software enterprises; Google cloud computing platform provide the application hosting, enterprise search and Internet application services to users. America Apps.gov website, providing commercial, social media, productivity applications such as SaaS service, realizes e-government collaboration. In our country, the cloud platform construction has made great progress, Beijing "auspicious clouds" project form technology, products and services integration. Shanghai's "sea of clouds" plan forms cloud computing demonstration platform for city management, e-government, and middle size enterprise.

Platform Design

In the overall architecture, public service platform can support open, flexible, collaborative IT technology system, to support enterprise management and services and to provide IT new value model for enterprise Informatization construction. Platform apply cloud services as the core design idea, build a unified business engine, information resources, management tools on the basis of the hardware equipment, and provide all kinds of services for enterprise users. Logically, platform service system is composed by the infrastructure layer, support layer and service layer. In addition, it provides uniform access interface, uniform standard specification, unified safety management measures for enterprise users ,and builds a full range of cloud computing services platform in one set of infrastructure service (IaaS), platform services (PaaS), software service (SaaS). The three services form the ecological chain of sustainable development. The overall architecture diagram is shown in Fig. 1.

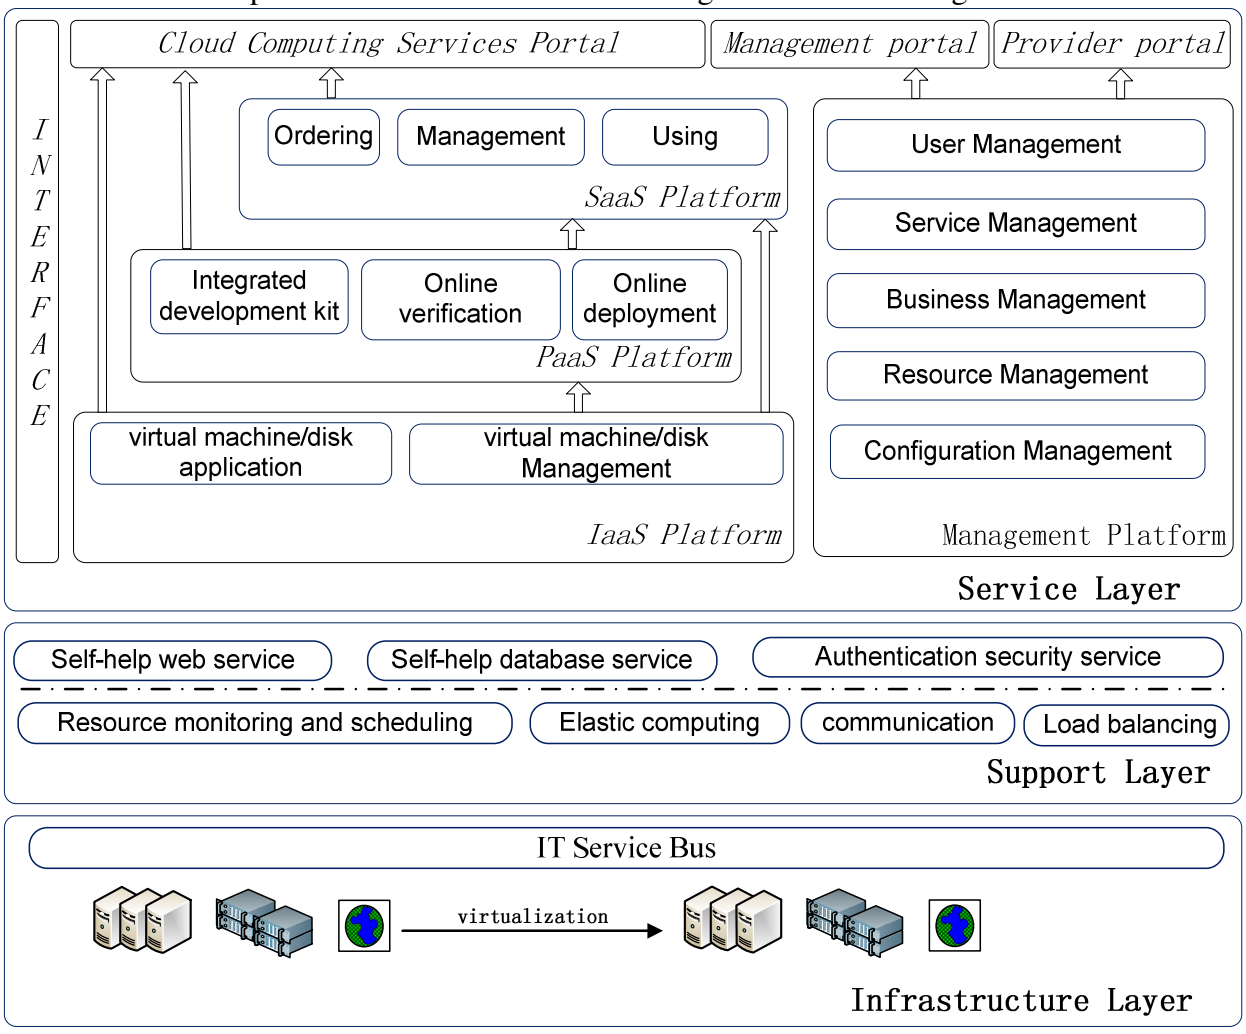

Fig.1 Cloud platform architecture

Infrastructure Layer. The infrastructure layer includes servers, storage, network, other physical equipment and virtual machine, virtual disk, virtual network, and so on. Using IT service bus, resource scheduling, application engine, data storage is packaged to service, through message communication realizing service invocation and interoperability; it provides not only registered operating environment, but also the technical support for upper layer.

Support Layer. Support layer mainly provides technical support for IaaS, PaaS, SaaS services, which can be divided into IaaS support platform, PaaS support platform and SaaS support platform, and is the bridge to infrastructure layer and the Foreign Service. It can call infrastructure service bus, managing virtual machine, and also can provide the universal interface such as self-service web services, self-help database services, and mass data processing services to service layer.

Service Layer. Service layer opens three different portal to users, including public services portal, management portal, and software vendor portal. Three portals are supported by four service platform, providing the corresponding services for different users. As the window of Foreign Service, the layer also provides uniform access interface, for authentication and data interaction between the software and platform.

IaaS Service Platform. IaaS service platform provides virtual hardware resources for enterprise users, including online applications and management of virtual machine and disk. Users do not need to buy hardware equipment, only build their own development environment through the internet.

PaaS Service Platform. PaaS services platform provides integrated development components and verification environment, which is a one-stop application platform covering the software life cycle. Using the platform, software developers can get integrated development component and unified access interface to quickly complete and release the project.

SaaS Service Platform. SaaS service platform provides a wide range of software services to users, including ordering, opening, managing, using and so on, users does not have to buy the software and hardware equipment, but to rent them by web browser.

Management Platform. Management platform is divided into IaaS management platform, PaaS management platform and SaaS management platform. It provides user management, service management, business management, resource management, and other functions for the cloud platform operators, and provides product management, business management, sandbox management, and other functions for software vendors. It establishes a unified information management, product management and resource management to improve public service ability specifically for middle size enterprises.

Public Service Interface. Public service platform provide a unified external access interface for software development companies and software vendors, including SSO authentication interface, SSO heartbeat interface, the client login interface, product access authentication interface, information interface, enterprise employees interface, and so on.

Key Technology

Rapid Deployment of Infrastructure Cluster. At present, the virtualization technology has basically realized the elastic expansion of resources that is increasing or decreasing the resources according to the variation of the load, in order to solve the conflict between resource supply and demand [6]. However, application system are usually not deployed in a virtual machine, but running in the virtual machine cluster, such as a typical Web system is made up of application server, database server, the cache server, load balance server. With the increase in business, the number of servers requires a corresponding increase. If only using virtualization technology, the server creation and deployment can be automatically implemented in minutes, but virtual networking and cluster configuration need take a couple of hours manually. Based on virtualization technology, the research realized the automatic virtual networking and cluster configuration, the time of resource adjustment shorted to minute level, and realized the scheduling of virtual clusters. The implementation method is shown in Fig.2.

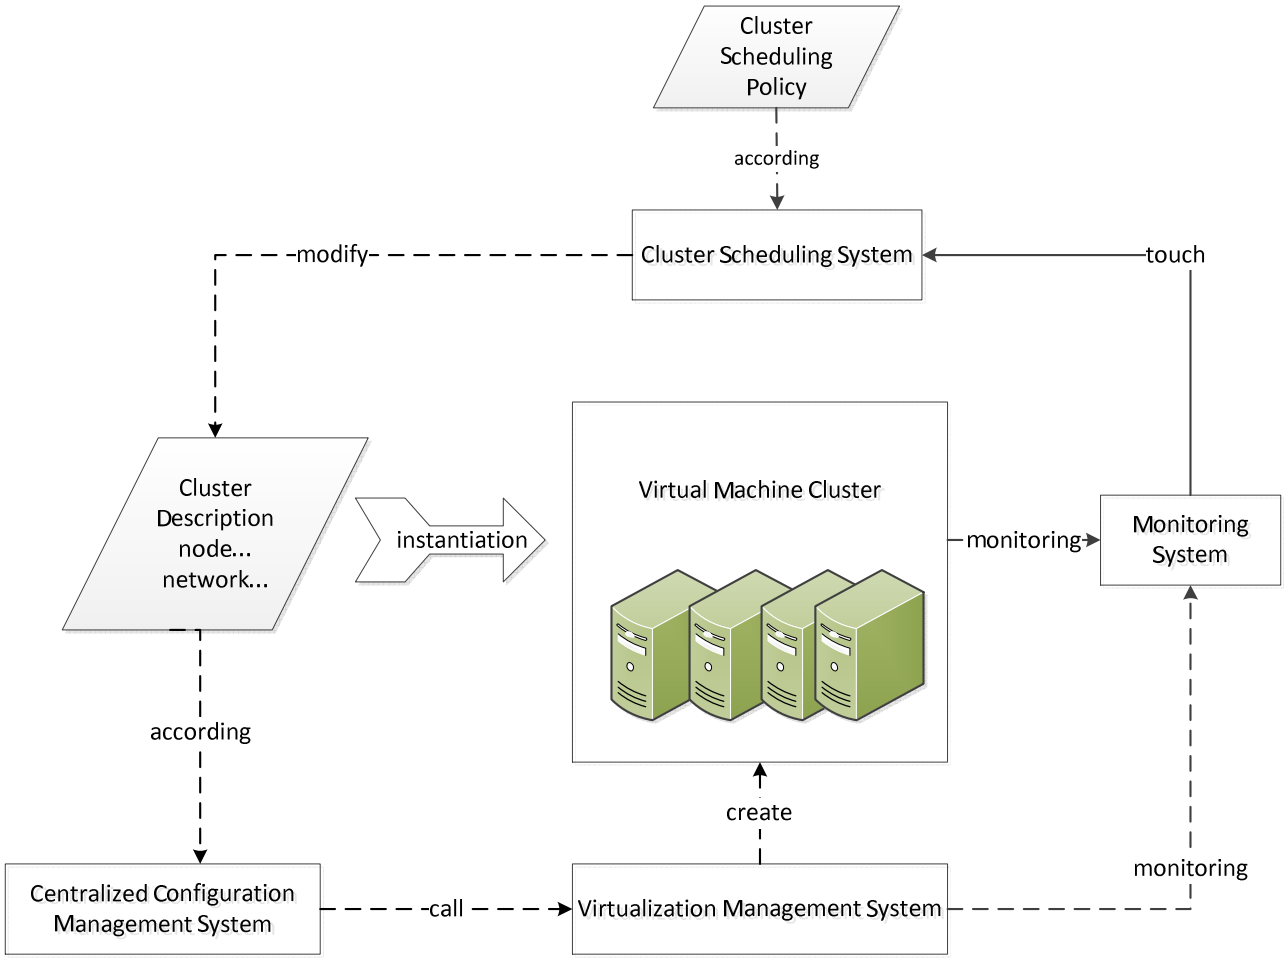

Fig.2 Rapid deployment of cluster

Practical steps are as follows:

- To describing the virtual cluster nodes and network using formal methods;
- To configure management system and create virtual cluster which according to the virtual cluster description and calling virtual management system or IaaS system
- To establish a unified monitoring system for hardware, virtual cluster and application;
- To make a cluster adjustment strategy by the monitoring indicators, cluster adjustment system modifies the description information based on the strategy, and thus triggers the cluster adjustment.

Online Deployment Technology. Online deployment system includes service system, management system and support system. Service system has unified entrance in the public services portal, which provides one-stop services such as product development, testing, and release for software development enterprises [9]. Management system extends corresponding module in the management portal, handles the work of component management, interface management, service application management, and release management and so on; Support system as a part of general support platform provides a common interface for service platform. Platform architecture diagram is shown in Fig. 3.

Service system. Service system provides a series of online service for software development enterprises. Integrated development kit includes a set of development component, the SDK, frameworks and access interface supporting C#.Net language and Java language, it allows users to quickly build locally software application. Online verification contains sandbox environment and debugging log. Online deployment support online operation of Web services and database service.

Management system. Management system contains the maintenance and information audit. Component information is development tools such as the SaaS model of product components, the SDK and product framework. Interface information is a series of operations including interface deployment, release interface, and monitoring.

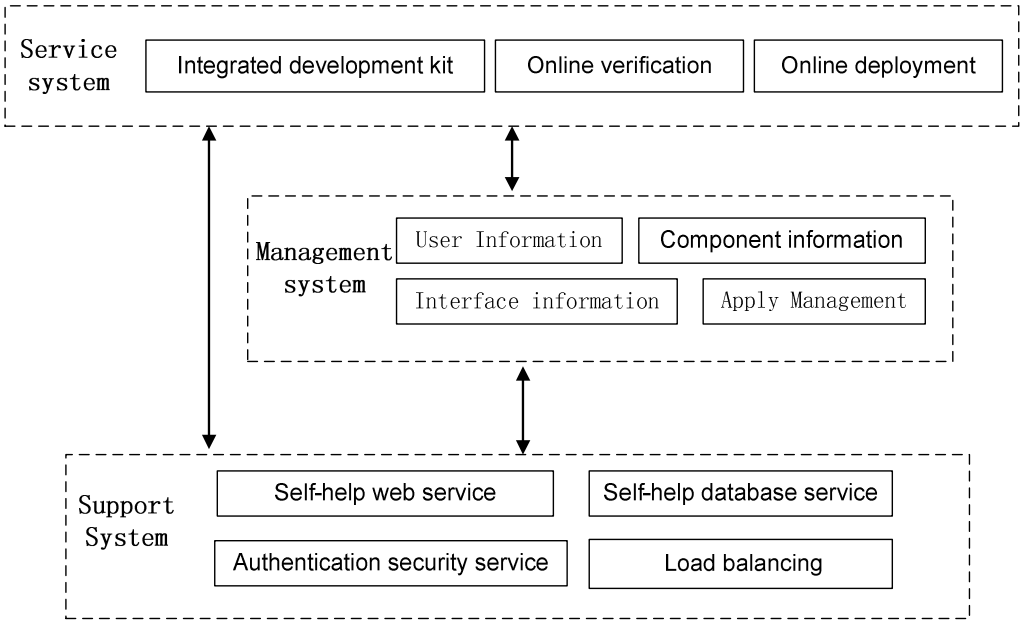

Fig.3 PaaS platform design

Support system. Support system consists of four parts. Self-help web service provides an interface which can automatically create the web service and is called by PaaS management system, it supports IIS and Tomcat Web server. Self-help database service provides a management interface which can automatically create the database, tables, views and stored procedures and is called by PaaS management system; Authentication security service support login authentication , single sign-on authentication and the client login authentication. Load balancing can make virtual resources extend according to application needs.

Software Service Integration Technology. Software service integration is the transformation of the application software in SaaS mode, so as to adapt to the demand of the cloud computing platform.

Traditional software transformation. The traditional software is generally a single tenant, and SaaS service requires multi tenant, therefore, multi tenant transformation is the key of software transformation. Among them, achieving data isolation among different users is the key link, which can be divided into database isolation, Schema isolation and Schema share.

Software Integration. After the cloud model transformation, software interface need be implemented in accordance with the standards, the interfaces include customer service interface and customer staff service interface to realize unified management, unified operation, unified single sign on service.

Conclusions

Based on the cloud computing service platform, we can enhance the rate of software and hardware resources, use enterprise management and business software online, and rapidly deploy product of its own. These effectively improve enterprise informatization level and expand sales channels.

Keywords: LBS, agriculture, logistics distribution, route planning, mobile clients.

Abstract: Lack of effective and real-time information in agricultural logistics distribution, which will cause the vehicle cannot accurately obtain the current location and cannot select the best distribution route, results in serious vehicle load and resource waste. Aiming at the problems, this paper proposes an logistics distribution vehicle scheduling system based on LBS. Using three-tier system architecture including application layer, logic layer and data layer, the system provides services of location, navigation, route planning, surrounding location query and agricultural news. Mobile clients can not only receive the latest news about agriculture, but also receive real-time vehicle location and query distribution route planning, which will help the delivery staff complete distribution tasks efficiently, consequently reduce logistics distribution costs and the waste of resources.

Introduction

Information services based on LBS have attracted more and more attention of society sectors. Today a variety of industries, especially in logistics, distribution and transportation, has put forward higher requirements on location-related services. On the basis of obtaining real-time vehicle location, users can further improve operational efficiency, reduce operating costs, improve service quality, reduce unnecessary waste and achieve real time monitor and management of the whole transportation links[1,2]. Moreover, with the popularity of smart phones and the rapid development of 3G networks, mobile application could provide users with more convenient information services.

Agricultural logistics distribution is a very important part throughout the supply chain of agricultural products. Its efficiency has a great impact on reducing logistics costs and improving customer service quality. Advanced information technologies, such as location-based services, could be used to agricultural logistics distribution enterprise. And this will optimize agricultural distribution paths, provide the shortest path for transportation staffs to travel, and minimize transportation costs. It will have a great significance on improving the efficiency of logistics enterprise resource consumption and the entire agricultural products supply chain.

System Design

Architecture. The system architecture consists of three-layer: application layer, logic layer and data layer. It is shown in Fig. 1.

1) The application layer is the portal of system. Users could access the system via the mobile client, PAD clients, laptops and other mobile devices.

2) The logic layer is the core layer of system. It consists of communication networks, mobile positioning gateways, web servers and GIS application servers.

The communication network connects users and service centers. It should be real-time response and accurately transmit users' requests and the response of service center. GSM, CDMA, GPRS and CDPD are common means of wireless communication. In addition, there are a number of optional communication links, such as wireless communication private network, or even wired telephone, paging and satellite communications networks, wireless LAN, and Bluetooth technology.

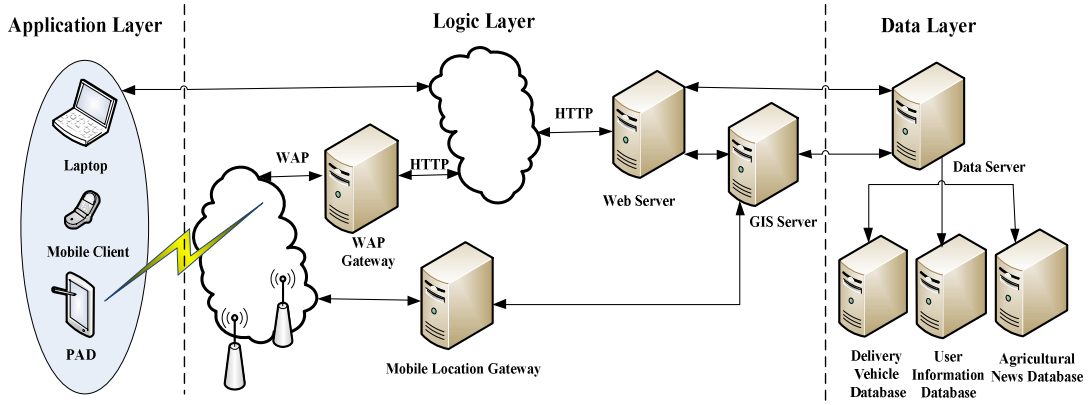

Fig.1 System Architecture

The mobile positioning gateway, web server and GIS application server are the core of location-based services. They are responsible not only for information exchange between servers and terminals, but also network interconnection between servers and the various sub-centers which includes location server and content providers[3,4]. Then they are in charge of completing the classification, record and forwarding of various kinds of information as well as monitoring the entire network.

3) The data layer is used for the unified management of all kinds of database and the flexible information exchange. It consists of databases which store all kinds of basic traffic information and related information, including the delivery vehicle information database, user information database and agricultural news database.

Positioning. Spatial positioning technology is the core of LBS. The main work flow of positioning is shown in Fig. 2.

Firstly, the user sends a location service request through a mobile terminal. Then the request, which should be forwarded through various communication gateways of mobile operators, is accepted by mobile location service center. After the certification, the mobile location service center invokes the positioning system to obtain the user's location information[5,6]. On the other hand, when the user has devices to automatically positioning, the mobile location service center could also obtain the user's location information through wireless networks. According to the location information, the mobile location service center could respond to the contents of services and forward them to the user through communication gateways. Finally, the user could obtain the respond to its service, such as displaying roadmap.

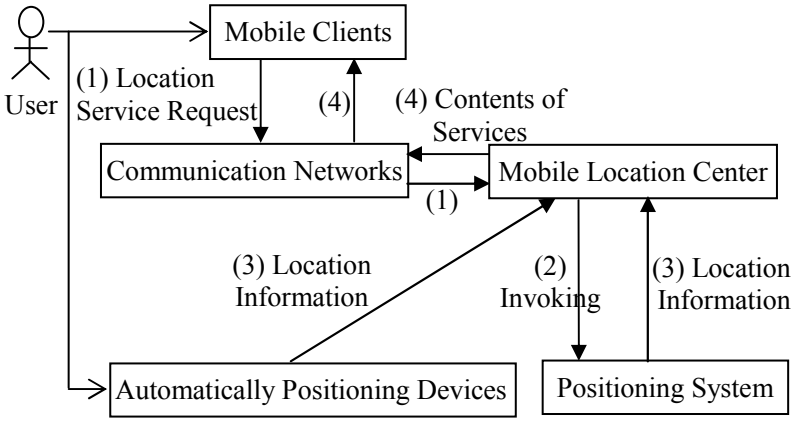

Fig.2 Work flow of Positioning

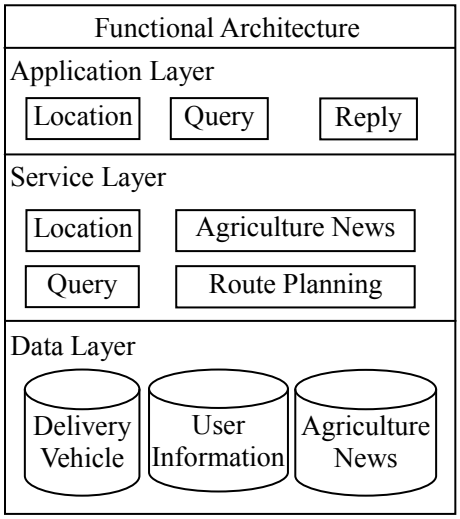

Fig.3 System Functional Architecture

Functions. As shown in Fig. 3, the functional architecture corresponds to the system architecture and consists of application layer, system service layer and data layer.

1) The application layer is used for the interaction between users and the system. This layer collects user location information, receives service requests and other user data, calls related services provided by the system, and then returns the result to the users.

2) The system service layer is the hub layer in the realization of the system. In addition to providing an answering service, this layer also provides traffic information services to the application layer, and manages the data layer simultaneously.

The system service layer is the core of the whole system. Information services provided by the layer include:

Agricultural information services. By using the service, users would obtain latest agricultural news on the mobile terminal. The news is pushed by the system.

Positioning services. By using the service, users could obtain themselves current location. This is done by positioning technology of location-based services.

Route planning services. When users need to query paths from the start to the destination, the system will return to three route planning schemes: public transport, walking and car. The result will be sent to the user through the application layer.

Location query services. By using the service, users could obtain a positional distribution map of nearby restaurants, hotels, gas stations, car parks and so on, as well as a convenient route to a specific location.

3) Data layer is used to store and provide traffic information. Data stored in this layer includes: delivery vehicle information data, agricultural news data and user information data.

System Implementation

The location-based service is the most important part of the system. The system uses map controls to locating and the Android SDK of AutoNavi to display map, and then further provides related services.

Location Service. Location-based service is the key of system. However, the traditional GPS technology has the following disadvantages: (1) it takes longer time to get navigation message; (2) it could not detect satellite signals in indoor; (3) it consumes more power. These shortcomings greatly limit the application of GPS technology in LBS. Therefore, the system uses a hybrid GPS positioning technology which is combined GPS with network positioning. The basic idea of this technology is to create a mobile communication network connected to a GPS reference network. This communication network monitors satellite status continuously. Then the auxiliary data from the GPS reference network is sent to the phone with built-in GPS receiver so as to speed up the startup process of the receiver[7]. Auxiliary data is used to improve the positioning accuracy and reduce the time of obtaining a signal. Furthermore, it is compatible with different positioning solutions.

Location function is custom implemented based on AutoNavi map. For cities which have better information network services, the positioning accuracy could achieve 100 meters and the shortest positioning cycle is 10 seconds.

Surrounding Location Query Services. This function mainly helps users query the surrounding location information. Through surveys on the user needs, the system provides four kinds of surrounding location services including gas stations, car parks, banks and service stations. It is faster and more convenient for users to directly select different service type by pop-up dialog box. For example, assuming that the user's location is currently positioned "weigongqiao". If the user selects "bank" mode, the map will display blue balloon icon to show all banks distribution around the "weigongqiao". Then you can click on the map to zoom in so as to see the details of specific location.

Route Planning. Route planning of the system is divided into three ways including walking, bus, and car. Firstly a user provides the starting address and the destination address to query as well as selects the positioning mode. Then the system will present the best route in the map with

different icons. For example, if the user selects "BIT" as the starting address and "Beijing Agricultural Building" as the destination address, and then selects "bus" mode, the map will present the shortest route with different icons.

Conclusions

As an important part of the development of agricultural logistics, agricultural logistics distribution has great significance on promoting the healthy development of modern agriculture. This paper addresses an agricultural logistics distribution vehicle system. Using three-tier system architecture including application layer, logic layer and data layer, the system provides services of location, navigation, route planning, surrounding location query and agricultural news. Mobile clients can not only receive the latest news about agriculture, but also receive real-time vehicle location and query distribution route planning, which will help the delivery staff complete distribution tasks efficiently, consequently reduce logistics distribution costs and the waste of resources. The system is easy to use. With the growing popularity of smart phones, the system has broad application prospects, not only in agricultural logistics distribution but also throughout the logistics industry.

Keywords: Public safety, Pedestrian facilities, Evacuation network, Spatial characteristics

Abstract. The spatial characteristic indicators of pedestrian facilities for evacuation are presented in order to contribute to the organization and management of pedestrian evacuation flow. An evacuation network is constructed based on the spatial layout of pedestrian facilities, in which the nodes represent moving sub-areas and two-way arc is on behalf of moving bottlenecks. Spatial characteristic indicators are built based on Multiple Origins Single Destination (MOSD) evacuation network including movement distance, movement amount, evacuation bottleneck, and evacuation aggregation extent. Through a case, the computation and application of the spatial characteristic indicators are presented in the layout analysis of pedestrian facilities, in which relevant improvement measures of spatial layout are advised.

Introduction

With a rapid expansion of the urban size and population, the large-scale activities of pedestrian became very frequent. In order to meet the demand of the city dweller for group activities and trips, the building size of pedestrian facilities is increasingly enlarged such as transportation hubs, stadiums, theatres, shopping center. The large pedestrian facilities have some characteristics, such as complex spatial layout, large-term construction cycle, organization difficulty of emergency evacuation and so on. Therefore, the spatial layout of large pedestrian facilities seriously affects pedestrian's normal or emergency evacuation. A reasonable spatial layout is conducive to improve the organization and management of pedestrian evacuation. The study on spatial characteristics of pedestrian facilities is a significant topic in pedestrian facilities construction.

In the research field of evacuation from a large pedestrian facilities, the work mainly include the evacuation sign[1], evacuation path or exit choice[2], evacuation design and evaluation[3], evacuation simulation[4], evacuation dynamics [5], etc… The theory and method about rational spatial layout or characteristics of large pedestrian facilities are relatively less researched.

In this paper, in order to form a reasonable spatial layout of the large pedestrian facilities, the physical space of pedestrian facilities is transform into an evacuation network based on evacuation bottleneck. And the space characteristics are analyzed based on evacuation network and evacuation path.

Spatial Layout of Pedestrian Facilities

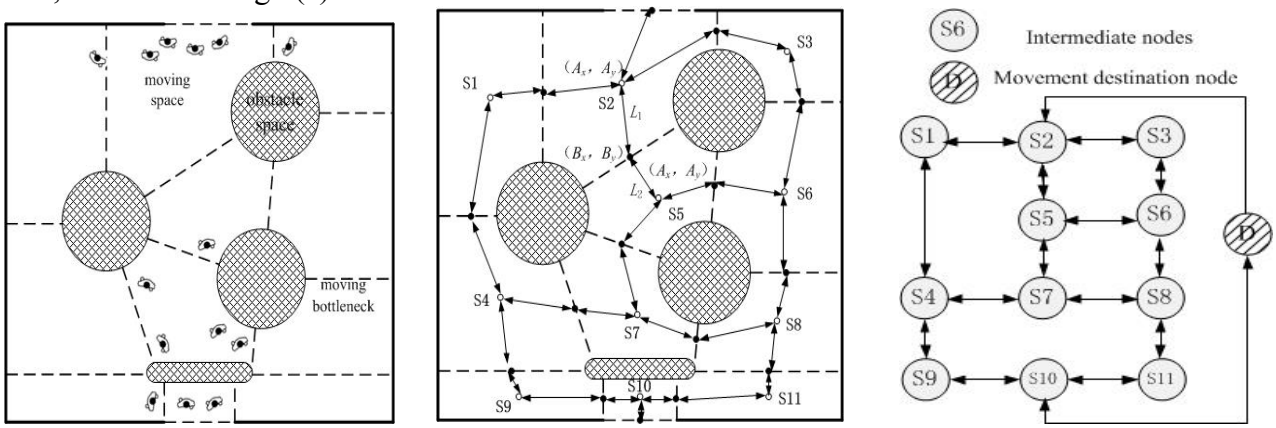
The physical space of pedestrian facilities can be divided into moving space and obstacle space. Moving space can be occupied by pedestrians such as walkways, corridor, stair, room, in which pedestrian can move to door and evacuate from room. Obstacle space is occupied by internal obstacles, which cannot be used for pedestrian movement, such as columns, walls, table, no-go room. When internal obstacle affected pedestrian movement, there will form a moving bottleneck. Fig.1(a) shows the moving space, obstacle space and moving bottleneck in pedestrian facilities.

The width of moving bottleneck is the shortest distance between two obstacles, through which pedestrian can walk in evacuation. To calculate the width of moving bottleneck, the outlines of the obstacle spaces are simplified to arc and line segment, as shown in Fig.1 (a).

Evacuation Network of Pedestrian Facilities

In pedestrian facilities, moving space can be divided into different and non-overlapped moving sub-areas by moving bottleneck (See Fig.1(a)). Evacuation network can be constructed based on moving space (See Fig.1(a)). Evacuation network is composed of two parts: nodes and two-way arc. The nodes represent moving sub-areas and two-way arc is on behalf of moving bottlenecks. In evacuation network, nodes are classified into three types: origin node, destination node and intermediate node, which respectively represents pedestrian moving sub-area of initial site, aim site and passing area.

In emergency or normal evacuation of pedestrian, pedestrian facilities can be defined as a Multiple Origins Single Destination (MOSD) evacuation network based on pedestrian evacuation flow, as shown in Fig.1(c).



(a) pedestrian facilities (b) evacuation network (c) MOSD network

Fig.1. The illustration of pedestrian facilities and evacuation and MOSD network

Spatial Characteristics of Pedestrian Facilities

Spatial characteristics of pedestrian facilities for evacuation are analyzed from the view of spatial layout, in which it is assumed that the shortest path with spatial distance is adopted in pedestrian evacuation.

Based on MOSD evacuation network, the characteristic indicators of pedestrian facilities for evacuation are presented as shown in table.1.

Table.1. The Characteristics Indicators of Pedestrian Facilities for Evacuation

Indicator category	Characterization
Evacuation distance	The distance from moving sub-areas to exit
Evacuation amount	The total amount of pedestrians movement distance
Evacuation bottleneck	The width of the moving bottleneck in pedestrians evacuation
Evacuation aggregation extent	The extent of pedestrians gathering in evacuation process

Examples

A shopping center is selected as an example to analysis the spatial characteristic indicators of pedestrian facilities for evacuation. The size of the facilities space is 20m × 20m, with two exits. It has 6 rectangular section counters and a circular section counters. The layout of internal obstacles in shopping center was shown in Fig.2. It is assumed that there are 346 people in the shopping center, and evenly distributed in moving space. In order to compute the characteristic indicators, the evacuation tree is constructed based on evacuation network and the shortest path with spatial distance. The evacuation networks and evacuation tree was shown in Fig.3.

The spatial characteristics indicators of shopping center are calculated as shown in table 2.

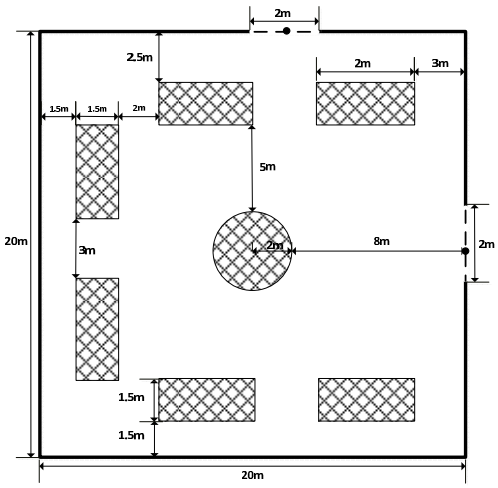


Fig.2. The illustration of the layout and size of obstacles in shopping center

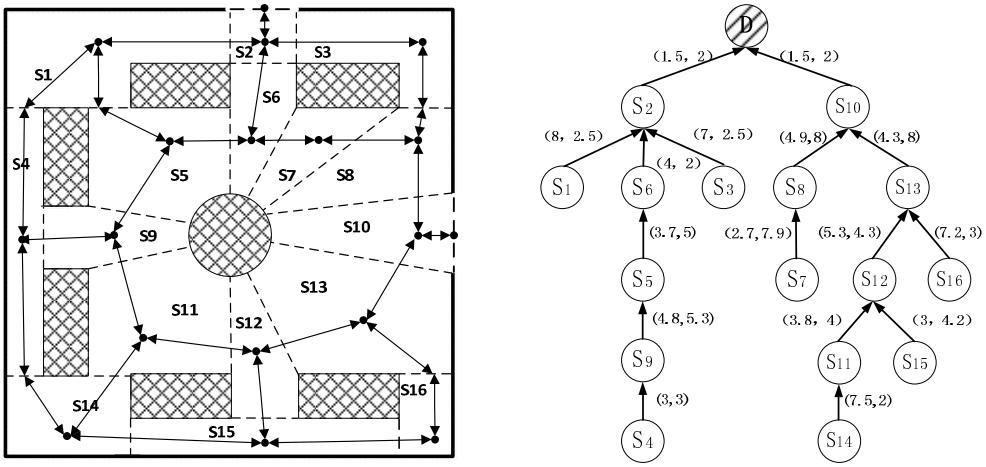
From table 2, it is can be found that there is a large difference between the maximum and average evacuation distance. So in order to shorten the pedestrian movement distance, it is advised to increase the number of safety exit or balance the relative position between the exit and obstacles. It is also found that there is a big difference between the maximum and minimum evacuation amount, which indicate that the spatial layout of the facility is unreasonable. It is advised that the counters that can attract more shoppers should be put to the location that nearest to the exit, so as to achieve the purpose of the reasonable layout of the pedestrian.

From Figure.3 and table 2, there are most people through the moving sub-area S2 to evacuate from shopping center, so it is advised to increase the size of sub-area S2.



(a) evacuation network (b) evacuation tree

Fig.3 The illustration evacuation networks and evacuation tree in shopping center

Conclusion

In the paper, the spatial characteristic indicators of pedestrian facilities for evacuation are presented based on an evacuation network. The physical space of pedestrian facilities can be divided into moving space and obstacle space, and the width of moving bottleneck is computed by the outlines of the obstacle spaces. The MOSD evacuation network is constructed based on the spatial layout of pedestrian facilities. Through an example, the spatial characteristic indicators of pedestrian facilities for evacuation are computed, based on the assumption that pedestrians evacuate from walking facilities along the shortest path with spatial distance. Simultaneously, an improvement in special layout of pedestrian facilities is advised.

Table .2. The characteristic indicators of pedestrian evacuation in shopping center

Indicators category	The name of indicators	Indicators value
Evacuation distance	Maximum distance	22.4m
	Average distance	9.64m
	Weighted average distance	10.2m
Evacuation amount	Total evacuation amount	3536.9m
	Maximum evacuation amount	536.4m
	Average evacuation amount	208.1m
	Minimum evacuation amount	7.5m
Evacuation bottleneck	Minimum bottleneck width	2m
	Maximum bottleneck width	16m
	Average bottleneck width	3.7m
	Weighted bottleneck width	21m
Evacuation aggregation extent	Maximum aggregation coefficient	3
	Average aggregation coefficient	0.94

Keywords: Project management information system; Building information model; BPS framework; Life cycle; Integrated Management

Abstract. According to the definition of building information model (BIM), authors compare the merits of traditional project management information system (PMIS) with the one based on the BIM model and BPS framework. Then authors approximately analyze the functions of the PMIS of this framework construction and discuss how this system will interpretably operate in life cycle. Finally authors give some advices on the issues in designing process.

Introduction

In the theoretical study of information systems, the vast majority of domestic research article will focus on the entire system architecture theory, but for the understanding of this architecture is still stuck in a pile of simple module level, or just based on project different construction period, the number of separate functional modules level combinations. Yet to propose a theory-based project management system, some of the theoretical framework advanced life-cycle management, integrated management systems integration to build the model. This article will focus on the establishment of such a model, and the model operation mechanism in the system.

Building Information Model Definition and Development Status

The so-called building information modeling (referred to as BIM) is the physical and functional characteristics of open industry standards in facilities, and projects related to the life cycle can be calculated or manifestations operation information. All information related to the organization and building information modeling in a continuous application, and allows access to, modify, and other operations. In a nutshell is, through a common standard (currently mainly IFC) and the integration of all relevant project information model.

From 2002, the company presented Autodesk BIM concept beginning, more and more software development companies have begun competing to design the model -based design software. There are Autodesk's Revit software, Bently company namesake software, Nemetschek Allplan software and Graphisoft 's ArchiCAD software company. The software has a dynamic process, 3D models and integrated document reporting. BIM 's core technology is a database of three-dimensional computer model of the formation, including in the design drawings (3D graphics, supplemented by various 2D sketch plane) is based, integrated from design to building construction until the end of the whole life cycle All works during the project information. Various kinds of information is always integrated in a three-dimensional model database. With BIM -based projects as building the system can continue to provide a variety of real-time data items in real time, complete and reliable information in real time and fully coordinated. BIM -based project system can be in a network environment, keep the information instantly refresh, and provide access, add, change, or delete operation, architects, engineers, construction workers, owners, end users and all users can be clearly related to the project system comprehensive understanding of the status of the project at this time. The information in building design, construction and operational management processes, accelerate

decision-making to promote and improve the quality of decision making, reduce project costs, so that the project to improve the quality and increase revenue.

Characteristics Compared with Traditional Built BIM Based Project Management Information System

Shortcomings of traditional construction project management information system

1) Due to the many aspects of the information transmission project management units and departments involved, the information entered can only stay in the engineering department or monomer interface, there are often lag, difficult to transmit to each other the whole project in a timely manner, of course, also hindered the entire project summary of the information, will inevitably lead to information island phenomenon.

2) Information about the progress of the project processing, investment, quality, contracts and other data, the number of large and dynamic changes, the traditional input information is difficult to timely summary, the parties involved often makes it difficult to grasp the feeling. Engineering drawings, documents, data and other documents, the number of large and generally stored in paper form, can not be random access to any time, affecting the efficient use of management information. Thus, information on all aspects of the construction has not formed a unified interface, can not form a whole.

3) Information on the use of building construction and management process will inevitably produce a large amount of information, and information for each array produces island situation, so that the information can not be shared and inefficient. More information can not be combined screening, meet the owners, contractors, subcontractors demand providers, contractors and other parties in each phase of the project.

Based BIM Construction Project Management Information System Benefits

According to the characteristic features of modern projects and project management theory, project management information system based on BIM features built in addition to the advantages of traditional management information systems, but also meet the following requirements:

1) Integrated management requirements in modern project management, there is a growing emphasis on integrated management, project management, integrated project management requires a higher level of systematic. Similarly, the integrated management information system is for the management requirements as well. For example: The goal of the project design, feasibility studies, decision-making, design and planning, supply, implement control, operation and management together to form an integrated management process; The objectives of the project, subsystems, resources, information, activities and organizations together, according to the plan so as to form a coordination complex operation; various project management functions, such as cost management, schedule management, quality management, contract management, information management, together, form an organic overall; integration and integration ¼ owners, contractors, design institutes, project management of all aspects of the management company.

2) Life cycle management requirements of modern construction projects required could be like other industrial sectors, in order to be able to provide end-use features as the main service. Life-cycle management philosophy is to ask the construction and management of projects to be considered for the platform in the project life-cycle process, the whole life of the project considering the various issues construction projects, making the overall goal of the project reach optimal. Reflected in the management information system construction, construction management information system is not just for the project implementation process, taking into account the management of information systems in business after completion of the works included in the operational phase of the application, so that both meet the needs of the owners actually work but also for the owners, end users, contractors, subcontractors, supervision agencies, such as the construction side provided some late summary data, which is currently lacking in many domestic research institute.

BPS System Architecture BIM Based Project Management Information System

BPS is also namely the browser server architecture. In this structure, the user through a Web browser, access the wide area network to achieve. Most of affairs to be achieved through the server side, between the terminal and the terminal server and the network connection, you can get real-time data transfer and integration process. Like system architecture that is the so-called three-layer structure of the network system, project management information system architecture shown in Figure 1.

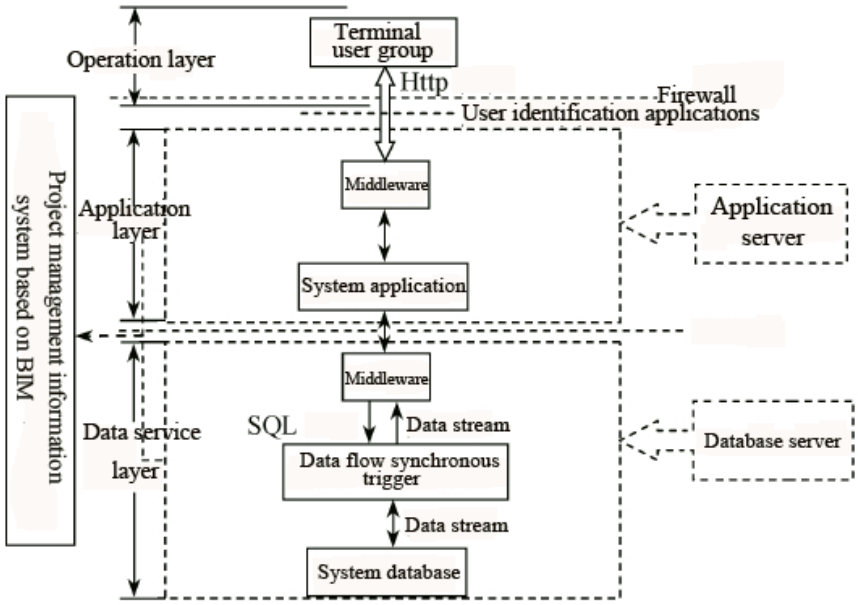

Fig.1. Network Architecture Project Management Information System

The first layer is the operating layer, also called user interface for end-user group (mean all people may operate the system, including the owner, design units, general contractor, subcontractors, construction side, end users, etc.) through a network provides browser, currently mainly Internet Explorer, users within the network permissible range (Line, VPN and even entire WAN), network protocols via Http, after identification, and make the appropriate operating authority empowered to enter the system, the associated operation; layer 2 is the application layer, the management information system applications loaded on the application server, the user receives access commands through middle ware, and then the results back to the user; layer 3 is a data services layer, middle ware connectivity through responsible for data processing instruction involves translation and processing, such as read, query, delete, add other operations.

Special attention is needed to load in the data between the database and middle ware is an important component stream synchronization trigger an implementation of BIM. Be achieved when the system database, which triggers an application is loaded all the data on the database table space. With this component, the current client application to issue any operating instructions (especially data-related operations, such as search, add, delete, etc.), you can synchronize each database triggers (eg: project planning document databases, contracts database, etc.) after integration, user feedback to the appropriate action. But in order to facilitate the understanding of the mechanism of the trigger, which was independent from the database table space. Information management systems in general, because there is no use of the data for all the components of the integrated database, so the system can not provide integrated data for each database, or that can not provide the data of each part of an integrated project management functions.

Architecture built using the BPS system because such system architecture also has the following advantages:

1) Low maintenance costs of the system architecture based on BPS basically just need major maintenance for the server, a single client even if the operating system is abnormal, it will not affect the server with other clients to run.

2) Upgrade costs and reduce development enterprises in the system upgrade, only the server applications and databases can be upgraded without the need for each client to upgrade the operating software and databases.

3) The server can run cross-platform server and client browsers on different platforms browser does not mutually exclusive, as is the Linux server browser, the client uses Windows IE browser still can exchange data and information.

4) The client runs the client load that is greatly reduced simply to exchange information with each other, and all operations are borne by the server, just to ensure fast processing speed of the server is running faster to complete the exchange of information with each other. Enable enterprises to reduce the use of client configuration requirements, us reducing the cost.

Conclusions

BIM-based project management information system through parametric simulation modeling technology that enables a computer to express all the information possessed by the project, the architectural design of information technology can be truly realized. With the development of BIM, not just the current advances in technology and upgrading of production will also be reflected in the transformation of organizational models and management, and long-term impact on people's thinking for the project. Although the system has not yet been devised, but with the deepening of theoretical discussion, practical work progressing, and such software for the entire construction industry will have a profound impact.

Study on Architecture of Power Marketing Management Information System based on Web Service

Qing Zhang

Department of Economic Management, North China Electric Power University,Baoding, China

23571581@qq.com

Keywords: web service; power marketing; management information system; architecture; system integration

Abstract. A multilayer distributed structure based on web service is put forward. The layer structure of power marketing business is described, based on the layer structure. The paper deduces that every business can be encapsulated by web service and each of them can communicate easily. The connection between the power marketing management information system and other systems is analyzed, and then the use of web service is presented to realize the integration between this system and the related systems. In the end, with the real example of a power marketing management information system, the solution for web service and the corresponding codes are presented.

Introduction

In recent years, the theoretical study of power marketing management information system has achieved some results, mainly into two categories, one is the study of software development from the perspective of the system structure and key technology system implementation; the other is from the management functional module business perspective on research system. Power Marketing Management Information System on the country has been put into operation, the application of the effect is not ideal, its main deficiencies as follows: First, marketing data or the provincial, city, county, four units of the power of decentralized management, failure to achieve full sharing of data; second, failed to properly resolve system compatibility and scalability, it is difficult to implement multiple power management modules organic integration of information services; third, it is difficult to achieve power marketing management information systems and other enterprise integration between information systems, such as integration with scheduling systems, production systems, substation operation system, line GIS, ERP, etc.. Some of these deficiencies in the due administration level, but is largely determined by the software development technology, the traditional two-tier C / S structure of the system communication applications on the Internet, CORBA, DCOM, etc., can not be achieved because of its own dedicated agreement difficult to achieve integration between heterogeneous systems.

XML Web Service is based on open standards and protocols, cross- platform, regardless of the development language, can cross the firewall, easy deployment and maintenance features, have become an ideal application integration technology. Therefore, we propose the use of Web Service technology to build power marketing management information system and related systems integration and resolve between.

Web Service Description

Web Service definitions

Currently Web Service is not a strict definition. Generally, Web Service component technology is an extension on the Internet, using a service-oriented architecture (SOA), which defines a set of standard protocol for the interface definition, method calls, registered Internet-based component and a variety of applications. Web Service with a cross-platform, regardless of the development language, can cross the firewall, easy deployment and maintenance features. Web Service function can be achieved with a simple response to user's requesting, it can be a more complex applications.

Once a Web Service published on the web, or other Web Service other applications can discover and invoke the services it provides.

Web Service Architecture

Web Service the architecture includes three kinds of entities and the three kinds of operation, the structure shown in Figure 1. Of which three kinds of entities are service providers, service requesters, service registry; 3 kinds of operations are publish, find, bind.

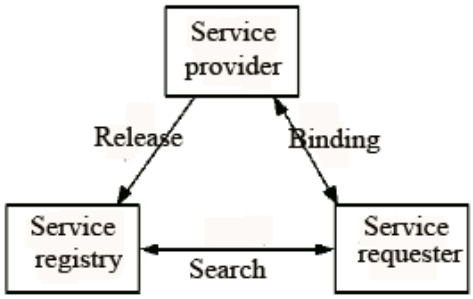

Fig.1. Web Service Architecture

(1) Web Service in the three kinds of entities: 1) Service Provider: the owner of the service, you can publish the services provided, and the use of their services to respond to the request; 2) Service requester: consumer services, in Find service registry services needed, and then call the service; 3) Service registry: also known as service agent, is used to register the service description. Service providers publish their services here; service requestor here to find the services they need to obtain binding information services.

(2) Web Service operation of three kinds: 1) Release: service providers to register their service registry provides functionality and access interface; 2) Find: Find a service requestor services needed to service registry, and receive calls service relevant information required; 3) Binding: service requester and service provider binding, which can use the services provided by the service provider.

Based on Web Service Power Marketing Management Information System Architecture

Software Architecture

Web Service based power marketing management information system using multi-tier distributed architecture, as shown in Table 1, including its four levels: the presentation layer, Web services layer, application service layer, the database service layer.

Table.1. Software Architecture

The presentation layer	Web browser.XML / HTML page. Applet. DCOM Clinet. CORRA Client
Web services layer	IIS. Apache. Web Logic
Application service layer	Web Services (business expanding, energy metering, electricity inspection, electricity tariffs, comprehensive analysis, reporting, icons statistics)
Data services layer	Oracle.SQL Server.Sysbasc.DB2 etc

(1) Presentation layer: mainly man-machine interface, responsible for inputting information display.

(2) Web services layer: mainly responsible for grant management and information presentation layer SOAP requests coming release.

(3) The application service layer: mainly responsible for handling transaction processing and logic operations to the Web Service package of services, depending on the power marketing business provides multiple Web Service.

(4) Data Services Layer: storage, and a variety of database management organization primarily responsible for the data.

System Hierarchy

According to the National Power Corporation "Power Marketing Management Information System Design Specification (Trial)" requirements, power marketing management information system is divided into layers of customer service, marketing, business layer, the quality of

management and marketing management decision support layer 4 levels. The relationship between the layers is shown in Figure 2.

Fig.2. System Hierarchy

(1) Customer Service Layer: The goal is to provide customers with efficient, convenient and high-quality service, establish a good corporate image of the service of power, for the power companies to win competitive advantage. The main contents include the operating room by means of a variety of services, call centers, Internet and customer site, etc., to provide customers with electricity regulations, electricity policy, knowledge of electricity, electricity technology and information services, such as electricity consumption, real acceptance by customers Newly submitted in a variety of ways, Capacity and electricity and other information queries and complaints and reports and consulting services and other services.

(2) Marketing business layer: the goal is to follow the flow of information marketing business standardized, scientific management principles for power marketing business to achieve fast, accurate processing. The main contents include processing new clothes, Capacity and power changes, contract management, electricity tariffs, fees and account management, energy management and metering and load management and other business processes.

(3) Marketing Quality Management: The objective is marketing business layer by layer, and customer service business process standards, business processing time, customer service assessment to monitor specific indicators of management functions, etc., to find problems quickly be reflected, urge relevant departments to rectify. The main contents include workflow optimization and supervision; marketing business auditing, contract management and implementation of complaint management.

(4) Marketing Management Decision Support layer: the goal is to develop a marketing strategy, marketing operations and development, customer information analysis, performance evaluation, public relations and corporate image design, management practices, and to provide a scientific basis for marketing decisions. The main contents include marketing business layer through the customer service level, quality management and other marketing information flow analysis applications, providing market operations and development, customer demand information, market forecasts and dynamic decision support information such research.

Integration with related systems

Power marketing management information system is not closed and isolated, but with other information systems are linked, there is a certain amount of information exchange and sharing. If you need to transfer the receivables electricity generation marketing and management information systems to financial management information system to establish accounts receivable, collection of data need to be passed after the recovery of funds to finance the tariff system and receive funds from the financial system to complete the arrival information manage cash flow; conducting marketing and management analysis, you can use the line carried GIS substations, lines, integrated query variable sets of statistics and analysis and forecasting; production MIS need to adjust the load from the relevant power marketing management information system information. In addition, there are some on the information exchange between the lower power supply companies, such as higher-level units need to subordinate units to check the quality of marketing efforts, the provincial power supply enterprise management decision analysis requires all cities within the province 's electricity

supply enterprise marketing relevant business data for statistical analysis. Therefore, power marketing management information system must achieve two major integrations: vertical integration and horizontal integration. Horizontal integration is mainly between the power marketing management information systems and other related subsystems integration of the unit, such as the production of MIS, line GIS, SCADA systems, financial MIS, ERP, CRM, OA, supplies MIS, MIS personnel, etc. integration; vertical integration is the integration between the major subordinate units power Marketing Management information System and superiors. Each subsystem does not require new development in the integration scenario, simply some functions can be called Web Service package into power marketing management information system, because power marketing management information system is constituted by a large number of Web Service, and they can also be other the system calls, thus achieving effective integration between systems.

Conclusions

In Web applications, dynamic web pages to achieve a lot of static functions can not be achieved, static web pages can also be part of the dynamic features, in appropriate circumstances, to achieve a certain dynamic web functions transferred to the more static pages to implementation, in order to get the system performance greatly improved, with storage exchange rate, feasible space for time, the growing emphasis on the user experience in the network, more user-centric today, this conversion has a wide range of practical value.

Analysis and Design of Supply Chain Inventory Management System under Internet of Things Environment

Zhi-Ping Peng

Department of Basic Education,Hebei Vocational College of Rail Transportation, ShiJiaZhuang, China

vicacer@163.com

Keywords: Supply Chain Inventory Management; Internet of Things

Abstract. The networking technology in warehouse management can be automated cargo management, operations and real-time access to inventory. Application networking technology greatly reduces the workload of warehouse management and unnecessary losses. Through the intelligent management of the goods, but also improve the utilization of warehouse space, to enable enterprises to understand the real-time inventory, thereby reducing inventory costs, improve the accuracy of inventory management.

Introduction

Warehouse Management, referring to the effective control of the transceiver, balances and other activities warehousing of goods, and its purpose is to ensure that the enterprise intact warehousing of goods, to ensure normal production and business activities, and activities on the basis of various types of goods status classification records to chart a clear way of expressing the quantity, quality aspects of the situation warehousing of goods, and general management in the form of the current geographic location, department, vesting orders and warehousing degree of dispersion conditions.

Internet of Things is an important part of a new generation of information technology. As the name suggests, things are material objects connected to the Internet. This has two meanings: First, the core and foundation of the Internet of Things is still, in the Internet based on the extension and expansion of the network; Second, the extension and expansion of its client to any goods and items of information exchange and communication. Things are "connected to the Internet." Things through IntelliSense, identification technology and pervasive computing, widely used in converged networks, and has therefore been called following the computer, the Internet world information industry development Third Wave. Things are applied to expand the internet, things are not so much the network, as it is a business and networking applications. Therefore, the application of innovation is the development of the core things to the user experience as the core of the development of innovative 2.0 is the soul of things.

Analysis of System Requirements

Things technology-based warehouse management system is the introduction of RFID technology in warehouse management, warehouse receiving inspection, storage, a library, transfer, shift library shift, inventory and other operational aspects of the data, automated data collection, ensure that all aspects of warehouse management data entry speed and accuracy to ensure timely and accurate grasp of corporate real inventory data, reasonable maintain and control inventory. Meanwhile, through scientific coding, also easily batch items on shelf life, such as management.

The new warehouse management system should meet the following aspects: a warehouse management information system usually rights management, data query, statistics and management functions; through the introduction of RFID technology can improve the accuracy of the goods query; through the introduction of RFID technology can improve the efficiency and quality of the library inventory operations; help companies reduce the cost of inventory management; operation of the system can accelerate the speed of goods out of stock, thereby increasing throughput inventory centers; able to give managers and decision-makers to provide timely and accurate inventory

information; able to automate the collection of inventory information, in order to achieve paperless inventory management.

According to the above requirements, based networking technologies warehouse management system should have the whole process automated warehouse operations; warehousing information instantly and effective feedback; update RFID tag collection and storage of data, ease of integration with other enterprise systems, ease of maintenance and scalability and other five basic functions.

System Architecture Analysis

At present, the common system architecture that there are two major: C/S architecture and B/S architecture. Advantages of C/S structure lies: in the data processing speed B/S fast that C/S is more conducive to handling large amounts of data. C/S technology is to design a flexible user interface, in order to fully meet the customer's own individual requirements. C/S has a strong interaction technique. In C/S, the client has a comprehensive application that has powerful features in an error message, online help, etc., and can switch between the subroutine. C/S mode provides a more secure access mode.

B/S structure also has its own advantages: B/S structure of information dissemination, data gathering speed faster; data sharing easy. B/S structure of the foreground client requirements low, avoid blindly caused a huge waste of hardware upgrades. Structure B/S mode is easy to expand and have a stronger information systems integration.

According to the actual needs of the system, combined with advanced maturity and B C/S structure / S structure, the system uses the architecture of C/S structure and B/S structure combining.

In the warehousing business internally, it takes into account the complex and onerous business client computing, the use of C/S structure of the transmission and processing of information within the system. In addition, the client can install the client software to improve data confidentiality, to prevent outside intrusion. B/S mode is mainly used to enhance the interactive warehouse management systems with external information systems, as well as publish and query public information, thereby improving the supply chain data sharing.

In the C/S structure section, networking technology into the warehouse management system to achieve automatic collection and processing of data. In order to achieve seamless RFID systems and warehouse management systems to achieve business process management and automation of the entire process of tracking and monitoring, the system will be C/S structure is divided into three layers.

The first layer is the data collection layer, mainly via RFID devices automatically collect data, including location RFID tags, electronic goods label, wireless RFID data collection terminals, automated guided vehicles.

The second layer is a data conversion layer, i.e., by wireless communication technology, to transfer the collected data after conversion to the server, including wireless access equipment and RFID middleware.

The third layer is the data management, data collection management, including database servers, network servers and other equipment and warehouse management system software.

System Functional Design

By utilizing the advantages of RFID technology, networking technology can strengthen warehouse management information system based on the enterprise storage features, optimize process, flexible configuration items, to provide customers with better management and data analysis basis. Through analysis, the RFID technology and enterprise storage processes combined into the new system features six modules: system management, basic data management, warehouse management, RFID dynamic management, statistical analysis, and financial management.

Systems Management: including contract management, role management, early warning management of the three functions. Contract management contract can query, add, modify, and void management. Role management can be associated with the operating system privileges to different

roles, and the roles assigned to specific operators realize the operator rights management. Warning is mainly about warehouse capacity management, inventory of goods and product shelf life for early warning. Depending on the type of storage, warehouse inventory warning conditions set and monitored. Warehouse capacity warning is the level of spare capacity on the warehouse early warning. Inventory Cargo warning, the number of goods in stock inventory customers early warning management, mainly for cargo minimum and maximum inventory value inventory value in inventory management for early warning. Shelf life warning is the shelf life of the goods on the early warning management.

Basic data management: including customer information management, employee information management, warehouse management, location management, cargo management, equipment management six functions. Customer information management can add, modify and delete customer information. Employee information management can add, modify and delete employee information. Warehouse Management can name for the warehouse, load-bearing capacity, volume, type, cost and other information processing to add, modify and void functions. Location management, including the type of management location, location and location rules governing appointment. Warehousing and cargo information can be managed to increase by location type, save, modify, and void function processing. Warehousing and cargo management can assign rules to increase by location rule, save, modify, and void function processing. By location booking appointments can add, modify and delete management. Cargo management including maintenance and cargo goods category archives management. By commodity maintenance can create, save, and delete categories of goods. File management via cargo can add, modify and delete details of the goods, the goods file management. Device Management

Including the consumption class device management, the device management and electronic machinery and equipment are management. Information storage devices need to add, modify and delete processing.

Inventory Management: The main system management module is responsible for the entire warehouse process control, its function modules include: storage management. The main function of this module are: procurement contracts signed by the purchasing department will convert pre Receipt; according to the pre- storage lists, check the spare location, identify a sufficient location and arrange location; storage of the goods when the goods Receipt itemized statement with the pre-check, check for input errors or omissions, goods name, quantity, etc. are the same. The agreement is permitted storage.

Goods inventory management. Including inventory planning, inventory -production, production and other capabilities inventory report card. With this feature you can add, audit, check inventory operations and other operations.

Transaction data management. Transaction data refers to data during the library carrying a tray Changes the number of items, mainly for the items in the library discontent whole tray needs to be adjusted some data related to the change. The main changes in the number of items handled tray, the tray to update data in the electronic tag items, while updating the corresponding data.

Database management. The most important function of this module is to audit the goods out of the library. Goods for the library system needs to be carefully audited, controlled goods information on the library notice and cargo container by the breakdown and handheld RFID reader to read electronic tags inside to see whether the input errors or omissions, cargo the name, quantity, etc., etc. are the same, if the same, then the use of facilities and equipment and warehouse regional planning system to determine the library platforms, completed by truck loading operations, the actual progress of jobs and other correction data input standby database as a repository add item database, a reduction of inventory database and print out the voucher documents and all kinds of practical library work report.

Reported loss management. Damaged goods can be generated by this single function, query, modify its operating status is processed. RFID dynamic is management. This module includes treating logistics management Basic information security

Equipment, implants, while taking advantage of reading and writing device for the collection of information across space stored within the RFID tag of its circulation, and then passed through the entire logistics information system database data conversion layer. This module is the cornerstone of the entire run RFID logistics information systems, while carrying the carrier of information flow and transfer function for the good functioning of the follow-up of each module plays maintain function.

Statistical Analysis. Statistical analysis module mainly pooled analysis of daily business, including: cost statistics, business statistics, product statistics, and customer statistics.

Financial management: including product account management, inventory management accounts of two functions. Account management products can query a product over a period of time out of storage conditions. Inventory account management can query a product over time inventory changes.

Conclusions

Use networking technology, companies can optimize the supply chain management system management processes and structure, improving the speed and accuracy of information transmission and physical match, improving the supply chain works. In this paper, the connotation of things, things key technology and supply chain management systems and many other aspects of analysis and discussion, completed the design, application and implementation of integrated design optimization system based on Internet of Things technology enterprise supply chain business processes.

A study on the data design of residents electronic health records system

Liu Ning

Jining Medical University, Jining, Shandong, 272067, China

yideyou9@163.com

Key words: residents electronic health records; Health records system; Database design

Abstract. Residents' health records is different from general hospital medical records, because it is not just about people receive medical service records, or a continuous, sustained, long-term, comprehensive, more extensive information about health information. This article according to the actual situation to the residents of electronic health records system database design are analyzed, and the residents' information table, the doctor information table, a medical information table, health file information table, travel information table and announcement information table 6 design of basic data table made a specific description.

Introduction

Both in developed and developing countries, health is the focus of attention, health for all human beings are trying to target, the basis for achieving this goal is to establish and implement a comprehensive health records, the health of all residents are unified into management. Residents' health records is different from general hospital medical records, because it is not just about people receive medical service records, or a continuous, sustained, long-term, comprehensive, more extensive information about health information. It has a high value in clinical practice, and more important to scientific research and medical education with valuable information. But each country's health records still exist many problems, for example, many countries and regions are still using paper files, most convenient also focused on the clinical medical purpose, the application range is not wide. Of course, this development with the basic national conditions of each country, the situation is closely related to social and medical conditions, and in the specific implementation process, also will have a lot of big hospital business management complex, hospital information there is no universal norms, standards and legal basis of the difficult problems such as lack of necessary data exchange. This article according to the actual situation to the residents of electronic health records system database design is analyzed, to provide the reference for related work.

The database design principles

In order to ensure the database of the clear and strong, as far as possible to maintain data integrity and cleanliness, custom database tables and fields demand as succinct as possible, redundant data should be as little as possible, which means that duplicate data should be reduced to a minimum. For example, the residents can't each table has a contact, or it will causing problems for data maintenance and consistency check. When a resident's contact details change, you need to update multiple tables to implement the action, if you have a table was unfortunately ignored, then it may lead to data inconsistency.

Database Concept Structure Design

After demand analysis, operation of the user's public electronic health records system has three roles; these are residents, doctors and administrators. System functions mainly include news announcement management, personnel management, hospital management, system management and so on four modules. Database concept structure design is to get the user demand for abstract information structure; typically with e-r diagram is described. ER diagram is a problem-oriented conceptual

model, which describes the representation does not involve data in the database and access methods. ER diagram of the basic elements that constitute the entity type (Entity) attributes (Attribute) and contact (Relationship), in this system, there are six major entities, that residents, doctors, administrators, archival records, bulletin information, medical records, travel information. Due to space limitations, this article is no longer listed ER diagram of the system.

The design of the database logic structure

According to the actual demand, general residents' database of electronic health records system mainly contains information table, the doctor information table, a medical information table, health file information table, travel information table and announcement information table 6 basic data tables.

The residents' information table. Residents information table including residents number, name, password, gender, date of birth, telephone number, home address, and notes and other basic information about the residents, their fields, type, length, etc. Specific requirements are shown in Table 1, residents' number that uniquely identifies the field as the residents, asking them to main keyword, and not be empty. In addition, it is only store the basic information such as date of birth, gender, don't store residents' age, height, weight and other information changes at any time.

Table 1 Residentss' information data table design

Field name	Instructions	Type	Length	Can be empty	Primary key
UserID	residents' Number	int	18	N	Y
xm	name	varchar	10	Y	N
mm	Password	varchar	20	Y	N
xb	gender	char	2	Y	N
sfzh	ID number	varchar	18	Y	N
phone	Phone	int	11	Y	N
birthdate	Date of birth	datatime	8	Y	N
adrress	Home address	varchar	50	Y	N
bz	Remark	varchar	100	Y	N

The doctors' information table. Residents' information table including Doctor No., name, password, gender and departments, where hospitals, job title, whether administrators, and notes and other information, specific requirements field, type, length, etc. As shown in Table 2. Residents of electronic health records system should be universal in all hospitals in a region, Therefore, doctors attribute not only to set the home department, but also indicate from which the hospital.

Table 2 The doctor information data table design

Field name	Instructions	Type	Length	Can be empty	Primary key
DocID	residents' Number	int	8	N	Y
xm	name	varchar	10	Y	N
mm	Password	varchar	20	Y	N
xb	gender	char	2	Y	N
ks	Subordinate departments	varchar	10	Y	N
hospital	The hospital	varchar	50	Y	N
zc	Title	varchar	10	Y	N
isAdmin	Whether the administrator	bit	1	Y	N
bz	Remark	varchar	100	Y	N

Medical Information Sheet. A medical information table including medical number, number, age, height, weight, family history of genetic, primary physicians and medical check-up date and other

information, generally will increase if there is a field of common diseases gastritis, tuberculosis, hepatitis, heart disease, etc. It is used to record whether the residents have similar medical history, specific requirements field, type, length, etc. As shown in Table 3. The table with the residents by resident ID information table associated, doctors and physicians through the main inspection information table associated with it. Residents of each physical examination in this table have a corresponding to a record, all the medical information can be retrieved by the resident population numbers.

Table 3 Medical information data table design

Field name	Instructions	Type	Length	Can be empty	Primary key
tjID	Medical ID	int	12	N	Y
userID	residents' Number	varchar	18	N	N
nl	Age	int	3	Y	N
tall	Height	int	4	Y	N
weight	Weight	int	3	Y	N
jbby	Gastritis	bit	1	Y	N
jbfjh	Tuberculosis	bit	1	Y	N
jbgy	Hepatitis	bit	1	Y	N
jbxzb	Heart disease	bit	1	Y	N
jzs	Family genetic history	varchar	2000	Y	N
tjDate	Examination date	datetime	8	N	N
docID	The main check doctor	int	8	N	N
bz	Remark	varchar	100	Y	N

Health Records Information Table. Health record information table includes the file number, the residents' number, age, treatment concluded, filing date, filing and physician notes and other information, its fields, type, length, etc. Specific requirements are shown in Table 4. The table with the residents by resident ID information table associated, doctors and physicians through the main inspection information table associated with it. Residents of visits or medical records in this table have corresponding a record, by residents' number can query to all the residents' health records.

Table 4 Health Record Information Data Table Design

Field name	Instructions	Type	Length	Can be empty	Primary key
recordID	File number	int	18	N	Y
userID	Residents' number	varchar	10	N	N
nl	Age	int	3	Y	N
jzjl	Conclusion visits	varchar	50	Y	N
recordDate	Filing date	datetime	8	N	N
docID	Filing Physician	int	8	N	N
bz	Remark	varchar	100	Y	N

Itinerary. The itinerary is the doctor's visits arrangements to facilitate medical appointments or medical residents, including stroke number, time, location, and other subjects and Memo fields are checked.

Table 5 The itinerary table

Field name	Instructions	Type	Length	Can be empty	Primary key
xcID	Tour Code	int	10	N	Y
xcDate	Time	datatime	8	Y	N
addr	Location	varchar	20	Y	N
km	Account	varchar	10	Y	N
bz	Remark	varchar	100	Y	N

Announcement Table. Announcement table used to store the system information announcement issued, including the number, title, content, authors and time and other fields.

Table 6 The Announcement Table

Field name	Instructions	Type	Length	Can be empty	Primary key
annID	Notice No.	int	10	N	Y
title	Title	varchar	30	N	N
content	Content	varchar	500	Y	N
author	Author	varchar	10	Y	N
addTime	Time	datatime	8	Y	N

Summary

Residents' electronic health records system is the core of human health throughout their entire life stages, the correct approach is "one filing, lifetime use", therefore, in the construction process, it should be possible to standardization, specialization, particularly in the design of the database requires a unified standard, so that different regions and hospital data can be generic, and so as to realize the co-construction and sharing, avoid detours, rework.

Research on emotional interaction design of mobile terminal application

Xiaomeng Mao

Shanghai JianQiao University, Shanghai 201319, China

25575355@qq.com

Keywords: emotional interaction design; interaction design; mobile terminal

Abstract. Discusses the realization of the path of the mobile terminal application software emotional interaction design. Analyzed design features of mobile terminal application software with combined hardware and software features. Analysis of the current features of emotional interaction design software applications. People's basic functional requirements of the mobile terminal application software for rising to the emotional and reflective user experience. Realize the emotional user experience needs improvements of interactive mode; interface design patterns; human-computer interaction applications feedback and deep-rooted experience of the target software features.

Introduction

In the rapid development of mobile terminals today, people's smart phones, tablet PCs have been a growing number of applications APP, APP and its people have noticed the interaction design of mobile terminals. More and more manufacturers are on this emerging platform for their own place. And how to make the APP in can meet the demand of the user experience of deeper more and more attention by people.

The characteristics of the mobile terminal application software interaction design

With the continuous development of mobile terminals, mobile terminal positioning of software are also constantly changing. From the initial PC-side software to be ported to the current mobile terminal centric software group, such as microblogging, letters and so on. Software mobile terminal relative to the desktop PC platform is unique in its development.

The use of the mobile terminal characteristics. The current mobile equipment has obtained huge development. Smart phones have greatly popularized the handset software applications. At present most of the software are developed a version of the mobile terminal, people can use these software using handheld devices anytime and anywhere.

The characteristic of mobile devices has decided the application on this platform has its features: First of all, as a result of the mobile terminal screen is limited by the size, and mobile terminal integrates many sensors, makes the application software are free to call these sensors for interaction design. And the use of the touch screen has been accepted by most users, accelerometer and gyroscope sensor such as there are a lot of potential.

The second is that people in the use of mobile device environment is more complex, probably on public transportation, the light of the road, is more likely to be in dim the pillow and so on. Most of the current application software design is more concise appearance and contrast the stronger or darker flexible interface design.

Finally, and using the characteristics of the important feature of mobile terminals, is that the current mobile terminal is highly personal and general use are relatively private. In today's software emphasized user, on the basis of the concept, everyone in a more intimate used for mobile terminal software. Each software is to some extent represents a personal login account on behalf of a piece of software added to a person with this software-centric social network.

Interaction characteristics of mobile terminal

Interaction design characteristics of the current mobile terminal platform software is given priority to with interaction of multiple sensor technology based on touch screen, touch with finger along with voice, accelerometer, gyroscope and light sensors and other operation mode of mobile terminals to interact.

An emotional interaction design

Emotional designs. Norman at three different levels of cognitive and emotional "Emotional Design" a book made of the process, namely visceral, behavioral and reflective. Among them, which is designed instinct-based design, which is a direct response to people usually easy to notice the parts, such as visual and other senses. The most direct can feel the change in the design to bring. For the behavior level design is perfect for the user's behavior. In Norman's theory, behavioral-level processing in three levels directly affect the other two levels of processing, because users use the product as the ultimate goal is to complete the goal. If it is not centered on behavior level, a product is likely to lose its real value. Rethinking design are the three levels of one of the most not intuitive, but reflect on design for product build long-term relationship with users. To match the instinct to design, to reflecting the emotional design, user will establish emotional bond with the product [1-3].

The realization of interaction design goal. Norman has not proposed method in the "emotional design" in the three-level theory in design practice and user studies. Alan cooper in the "About face 3" will correspond to the three levels of the three target user. Alan cooper mentioned three objectives were: experience goals; ultimate goal and purpose in life. At this time of everyone is talking about the user experience, user experience seems to be beyond some of the important indicators into the highest goal of interaction design. Because human beings are emotional animals, people in the use of the product, can really influenced by product design, if the experience is not good, people feel stupid or uncomfortable, will naturally cause changes leading to the user of the product to disgust.

Users in the use of a product are the fundamental motivation for the product they need to help them complete a basic goal that is the ultimate goal. Users before using this product will have a desired result, satisfied the user of this is become one of the most important goals determine product overall experience.

People in the use of products, there will be a situation of the vision, it is beyond the product design, and life goals expressed the user's personal desire. This is why the user to complete the final goal of drive and motivation, or is the real purpose behind the final goal. This can be embodied in, users expect a better life, to work in some way, achieving ideal and so on.

In interaction design, the current mainstream direction is to achieve continuously improve people's interaction experience. This is in interactive design experience goals.

Emotional interaction designs. Emotional interaction design is before two characteristics after interaction design to satisfy the need to achieve a new goal. The purpose is to let users to human-computer interaction feel more human, and not just the interaction with machines. At the same time, the emotional interaction design is through the different form to the user to create a comprehensive experience, the experience may through a humanized interface design can reflect, may need a whole set of the man-machine interaction pattern can reflect. In the mobile terminal platform, can use a variety of integrated equipment, emotional interaction design goal becomes more likely to be fully realized.

The main form of the mobile terminal design reflects the emotional interaction

Reflect the main form of emotional interaction. Product main forms including reflect emotional interaction: the application software of main interaction patterns; interface design pattern; application of human-computer interaction feedback; software functions of deep experience goals.

First, the interaction patterns reflected in the main interactively products. Most current software interaction patterns with touch screen click, sliding. There is also some frontier software using the

touch screen gestures. To clear the software, for example, which is a wholly gestures notepad software, it does not have a dedicated button controls. Users only need to be on a touch screen to sign all the operation can complete the software. This concerned in the interaction design of mobile terminal software has caused many discussions in the crowd.

The second, the interface design pattern is embodied in the basic set up to meet the viewing habits of people and the interaction of people used to give priority to. After the multi-touch screen is widely used, people mainly use finger interactions; it is the interface controls such as buttons on the new requirements are put forward. So much of the current mobile terminal software to meet people mainly controls the size of a finger, fully embodies the design concept for the center with itself characteristic.

Third, feedback, people in the use of mobile terminal the easiest question is that how the machine feedback has been done to the people. In a traditional PC, due to equipment limited, only through sound and image to feedback to the user. The mobile terminal has its advantages, such as vibration. Android platform of smart phones generally set with a touch of micro vibration, to make up for the touch screen brings feedback problem.

Fourth, behind the function of the software to provide people, how to make software for a long time remain in the user's mobile terminal in a matter of great concern to all manufacturers. Such as gaming companies, how to make the game with a viscous, let the user as long as possible to maintain interest in the game; Functional software such as notepad, to remind the software, how to enable users to focus on software, and so on for a long time. This requires the function of software and content ideas can satisfy the user's deep emotional needs.

Emotional interaction design application analysis. Currently it has been a part of the application software has been used emotional interaction design concept. Because the target user experience is different, the use of application software for mobile terminal characteristics has done many improvements.

In Netease news, for example, as a web page to mobile client transplantation, the user carrying the expanded scope of the availability of the user is enhanced several tasks. Netease news has chosen the people most concerned about a few big news classification, and by as much as possible on a mobile device within the limited screen size to display the need of news content. Netease news compared with several other client differences is interactive. In each of the news, the user can press carried a message to this thread, which has played a significant use of the characteristics of mobile devices. To the people to the discussion of some hot news created platform, it in people's emotional have a way of the communication. At the same time, netease news mobile client for individual users in the use of background characteristics joined the night mode, fully consider the use environment of the iPhone and other mobile devices, by lowering the brightness contrast and color Settings interface, let people browse news experience more comfortable in bed. For users in different, netease news using GPS module to set the automatic location of the device and display the local news and weather patterns. This module Settings with around characteristics to people's emotional also brought a lot of help, people like to communicate with a local press officer. In pieces give full play to the user time, netease news list of news column was optimized [5-7]. Netease news under the headline in one sentence: sum up the main content of the news, let users can browse the news list roughly to master the main content of the news, when I was greatly save the user's valuable time.

A current hot game software called "you draw I guess," the game comes from a very common game. But be transplanted into represented by touch screen mobile terminal platform, after the game, not only has realized the inherited the interaction of the real game experience, more to extend people's emotional interaction.

In real life, "I guess you must be a few people at the same time in one place. Speculation and the game process and graffiti has occupied the people a lot of time. In the mobile client version you draw I guess, users can easily use the networking of the mobile devices and any people all over the world. Greatly enhance the space range over the game. On the game time, as a result of simultaneous set the game, the user can at any time to open the game playing with other users. Thus caused a total of time and space, in this time, there is no time difference between people, there is no distance [8]. For people

of the quickening pace of life today, this is a very good with your family, friends of communication space.

Emotional interaction design

In the latest release iPhone5s, integrates let a person feel strange and familiar with the equipment - the fingerprint sensor. Although fingerprint sensor has been applied in early on the PC, but for the mobile terminals equipped with this device has a deeper meaning. Because it can reflect the characteristics of mobile terminal - more personal, the role of the mobile terminal from ordinary personal electronic devices gradually turned into an interface of a natural person in the online world. With the fingerprint sensor, after people get rid of the login user and password in the various application software process, greatly improving the user experience.

Now, more and more applications to focus on the comprehensive utilization that various sensors on mobile devices. It's including the gravity sensor, gyroscope, and touch screen, GPS positioning module and a microphone and camera. So behind in providing people with good software interaction, are actually in the direct indirect emotionally to people to support, make people in reducing the consumption of emotion in human-computer interaction. And some social, interpersonal communication for the application of the ultimate goal is to meet the emotional needs of the people higher [9].

Interaction design is still considered the most current whole our common humanity, in the optimization of user experience on most are based on human cognitive or universal human common psychological basis. When interaction design to continue developing the most common user experience are basically completed, the user experience should be more on the basis of the different culture background and experience background, the optimization of users to make more detailed close [10]. Let people feel when using application software is not only complete the task, but in a way of life experience, feel closer to his ideal.

Conclusion

At present, mobile devices have greatly changed people's life, way of communication; at the same time also become an important part of people life. It is the need for interaction has not only stayed on the user experience, but by the higher spiritual and cultural needs. With the help of the current the most advanced personal communications terminal, set up a full range of communication through the network. Not only on the exchange of information, but also on the emotional culture communication. In the future mobile terminal application design, the product will be more people to consider cultural differences, national identity, using the background and personalized interaction design experience.

Keywords: RFID technology; GSM system; intelligent attendance checking

Abstract: Nowadays many colleges use galaxy network technology as well as computer and Internet technology, give full play to various technical means of information network and make good use of various kinds of various education, scientific research and information resources, develop all kinds of application system and management system, realize network interaction management, and thus fully promote the development of higher education informatization. An intelligent classroom attendance checking system is introduced in this paper. As an important part of campus management system, this system can intelligently complete examining students' attendance. In addition, this system can automatically collect data information in real time, automatically analyze and process the collected data, report these data using visual interface, and thus intelligently implement SMS notification at the same time. The traditional way is to assess, record and manage the attendance of students by roll call or magnetic card, which not only consumes the time, but also interferes with each other; while RFID student attendance application system is applied to manage the attendance of students using RFID technology, which not only completes the attendance checking conveniently and quickly, but also saves resources.

Preface

In recent years, RFID technology has been applied in many fields, including logistics, retail industry, manufacturing industry, clothing industry, medical care, identification, anti-counterfeiting, asset management, food, animal identification, libraries, automobile industry as well as aerospace and military affairs. It has had a significant impact on improving people's quality of life, enhancing the economic efficiency of enterprises, strengthening public safety and improving the level of social information.

1. Overall design scheme of the system

When using this system, students with RFID chip student card can complete auto-induction attendance checking when entering the classroom door without the need for touching clocking-in machine, and many people can achieve attendance checking when entering the door of school buildings simultaneously without the need for queuing; meanwhile, the reader can be controlled to upload the received information to computer terminal for processing, thus accurately recording the entering and leaving time of students as well as other information. The information of students who failed to attend the class punctually will be sent to the relevant person in charge of the attendance affairs through GSM system in the form of text messages. The block diagram is shown in Figure 1.

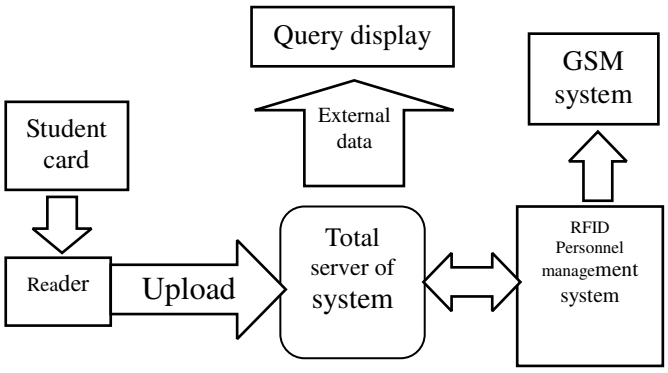

Figure 1 Block diagram of classroom attendance system

2. **RFID chip**

RFID chip is manufactured with CY-14443A series RF reader module. Using the chip dedicated for contactless reader based on ISO14443 standard, this module adopts 0.6 micron CMOS EEPROM technology, supports ISO14443typeA protocol, and also supports MIFARE standard encryption algorithm. An analog modulation and demodulation circuit is highly integrated in the chip, so the chip can work using a minimal amount of peripheral circuits, support UART interface (-C), I2C interface (-U) or SPI interface (-P); in addition, a digital circuit has two voltage working modes, namely TTL and CMOS. The chip is especially suitable for the reader application of billing system or identification system under ISO14443 standard, including water and electricity meter, vending machine, access control and telephone.

CY-14443A Series support Mifare One S50, S70, Ultra Light & Mifare Pro, FM11RF08 and other compatible cards. The cards can be detected automatically, and automatic card detection is the default state. CY-14443A series are all equipped with onboard built-in antenna, and external antennal can be connected. The advantages of built-in antenna are to improve the integration, read the card with a size of less than 6cm, basically meet most of the design needs without the need for externally connecting large antenna, and connect to the external antenna without the need for replacing the circuit, so as to improve the reusability of the system and significantly reduce the costs. In addition, the reading head of built-in antenna can be used as an active antenna. This module also adds 4kBits EEPROM, EEPROM byte addresses from 0x00 to 0x1FF to read PN and SN of PCD.

Single-chip microcomputer and RF module conduct communication using SC2 interface, with simple communication interface, as shown in Figure 2:

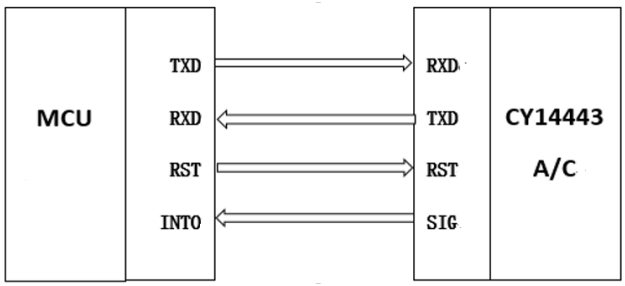

Figure 2 Serial connection mode of CY-14443A series RF reading and writing module

3. Software part

The central management and control software is the center of classroom attendance system. It is used to control the operating state of reader and RFID card as well as conduct statistical processing for the data of students when going into or leaving the classroom. The main features are as follows: it is easy to operate and control this software; the reader can be controlled and the data

can be transmitted through serial communication protocols; it is easy and convenient to input student information, with good maintenance and confidentiality; the statistical processing can be conducted for data quickly; this software has perfect data query functions.

The functional modules of system software mainly includes: user login module, real-time report and classroom leaving display module, reader control module, database management module and statistical processing module of data, as shown in Figure 3:

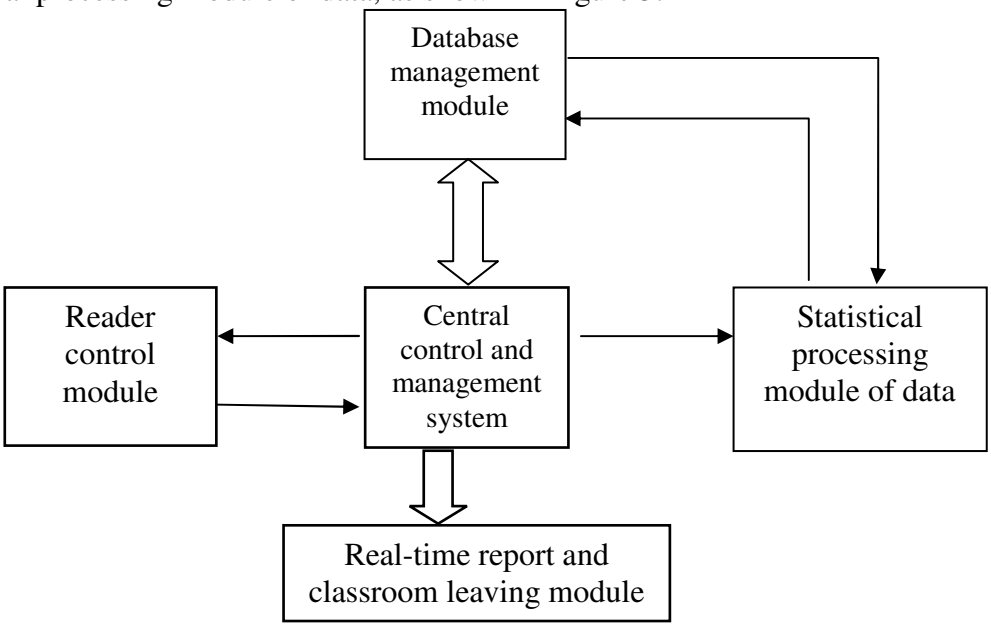

Figure 3 Software system display module

textBox3duanxinneirong.Text);
                MessageBox.Show("Sent successfully");
            }
            else
            {
                MessageBox.Show("Please open the serial port");
            }
        }
```

5. Conclusion

This paper studies the intelligent check-in of students through RFID system. The relevant data are displayed and processed at computer terminal, and intelligent SMS notification is conducted via GSM system. In the entire study and experiment process, good results have been achieved. The system can be installed in many places of the campus, and teachers and instructors can realize the real-time monitoring of student distribution in the campus only after logging in computer terminal system, thus greatly improving the efficiency of student management by colleges and universities. Moreover, this system can be used as an intelligent teacher conference report system, and it can be specifically used for relevant applications in governments, enterprises and other departments as an intelligent teacher conference report system, thus greatly improving the efficiency of conference management. It is believed that with the rapid development of RFID technology, this system will be continuously improved and widely used.

Inflation Forecast Based on BP Neural Network Model

Yuechun Wen[a], Lina Tan[b*] Hailong Wu[c]

School of Economics & Management Tongji University Shanghai, China

[a]wenyc1965@126.com, [b]candytln@163.com, [c]hailongwoo@gmail.com

Keywords: BP Neural Network Model; Inflation Forecast; CPI

Abstract. This paper analyzes inflation forecast based on BP neural network model. Firstly, it reviews some references about BP neural network and finds that it is a nonlinear adaptive data-driven model with induction ability and a wide range of function approximation ability so that BP neural network could be applied into forecast research. Secondly, it builds up the BP neural network model to predict CPI, selecting the four indicators, which are excess liquidity, exchange rates, inflation expectation and macro-economic leading index. Then it carries out empirical experiment and takes advantage of the monthly data of the above four indicators from March 2005 to December 2012 to forecast CPI. The results show that when prediction period is 3 months, the maximum absolute error between forecast value and real value is 0.0139, and the minimum absolute error is 0.0005. When prediction period is 6 months, the maximum absolute error is not more than 0.02. It proves that BP neural network model can predict coming CPI trend at least 6 months according to the existing data and it means it is suitable for the study of inflation forecast.

Introduction

Since the 1990s last century, inflation has gradually become one of the world's core economic issues of common concern. Inflation can distort price, erode of savings and inhibit investment, hindering the healthy development of the economy. Therefore, how to effectively control inflation is the focus of monetary policy in a national central bank. Because there exists a time lag of monetary policy in the implementation process, how to accurately predict inflation is particularly important, in order to better achieve the goal of monetary policy. In this context, inflation forecast is of great practical significance.

Literature References

BP Neural Network (Back Propagation Network) was created by Rumelhart and McClell [1] in 1985, which is a kind of multilayer feed-forward network structure. It takes advantages of error back propagation algorithm to train network output and the outputs are commonly between 0 and 1. Neural network has the following four advantages which make it suitable for time variables forecast research.

First of all, compared with traditional theoretical model, neural network is an adaptive data-driven model and it only needs a few assumptions to build a model for the problem. So even if time variables' internal formation pattern is unknown or hard to describe, neural network can also learn from the training samples and the form a stable function relationship. Based on this characteristic, Han [2], Kuo & Sheng-Feng [3] pointed out that neural network can be seen as a multivariable, nonlinear and nonparametric statistical model.

Secondly, neural network has induction ability, and even if the training sample has a large amount of noise information, it can also correctly infer the trend of time variable through study. This point is very important, because forecast itself is to predict the future behavior based on the past and present through observation data.

Thirdly, the neural network has a wide range of function approximation ability. Hong[4], Huang[5] found that neural network could approximate any continuous function with arbitrary precision. Any prediction model assumes that time series have internal relationship between its past, other related variables (input variables) and future variables (target variable).

Last but not the least, neural network is nonlinear. Traditional forecast models such as ARIMA hypothesize inner forming process of time variables is linear, but Barra[6] pointed out that real economic system is generally nonlinear. So it is inappropriate to build linear models to estimate nonlinear time variable, which would easily lead to a larger prediction error. The nonlinear characteristics of neural network make it suitable for the nonlinear part of the time series and improve the forecast precision.

BP neural network model analysis

In order to facilitate the research, this model selects monthly data of the four indicators, which are excess liquidity, exchange rates, inflation expectation and macro- economic leading index from March 2005 to December 2012 to do forecast. The data is classified in the first place and generally 80% of input and target data are used to train the network and the remaining 20% are used to test the network. In this paper, the prediction period of neural network is classified into 3 months and 6 months, respectively, thus there are two different data sets and specific data classification is shown in the table below:

The network layer. Wang and Jianjun[7] have proved that a feed forward neural network containing only one hidden layer can approximate any continuous function, so this paper uses a three layers BP neural network structure that contains only one hidden layer.

Number of neurons in hidden layer. Determining the number of hidden layer's neurons has always been a very complex problem, because the number directly affects the nonlinear performance of the network. According to the experience, there are two reference formulas to determine the optimal number of hidden layer's neurons:

(1)$m = 2n + 1$, m is the number of hidden layer's neurons and n is the number of input layer's neurons.

(2)$m = \sqrt{\mathrm{n} + \mathrm{n}_1} + \alpha$, n_1 is the number of output layer's neurons and α is a constant between 1to10.

In this paper, the input layer has four input variables and the output layer has one variable. According to the above formula, the optimal number of hidden layer's neurons is 4 ~ 13, but the specific number would be determined by the network training error.

Transfer and training function. At present, there are three kinds of neural network transfer function: Log-sigmoid, Purelin and Tan-sigmoid. Log-sigmoid and Tan-sigmoid are s-shaped function while Purelin is linear function. Tan-sigmoid is suitable for input and output between -1 to 1, in line with the characteristics of input and output's normalized vector, therefore, it is taken as the transfer function of hidden and output layer. Traingdx is taken as training function, and this function's learning algorithm uses gradient descent momentum method. Moreover, the learning rate does not need to set additionally, which can automatically adjust according to the training process.

Steps training. Some related research pointed out that the accuracy of network had a great influence on the prediction: if it has low accuracy, forecast ability of the network is poor while high accuracy would easily lead to cause over fitting and the network's generalization ability is weak as

well. To avoid this phenomenon, this paper sets network's training to 1000 steps, and accuracy of training to 0.01. Other parameter values of the network are shown as follows:

Experiment and analysis

According to the above set of BP neural network parameters (programs are written using MatlabR2009b), and then specific network training can be carried out.

Determination of hidden layer neurons' number. In the process of BP neural network training, it needs to determine the optimal number of hidden layer's neurons, and in the former part of the paper, the number of neurons is temporarily determined as 4 to 13. Therefore, experiments were performed with different number of neurons. The selection criterion is the minimum value of network's error and the evaluation index is the mean absolute error (MAE).

There are 2 different prediction periods in the paper and both need to determine the optimal number of hidden layer's neurons. To make it simplified, Table 1 only gives neural network training results for prediction period as 3 months.

Table 1 Performance of different neurons table (prediction period is 3 months)

Number of neurons in hidden layer	Training error	Training steps	Number of neurons in hidden layer	Training error	Training steps
4	0.0097	298	9	0.0070	246
5	0.0048	145	10	0.0079	329
6	0.0061	234	11	0.0075	332
7	0.0053	228	12	0.0085	224
8	0.0039	131	13	0.0064	244

The experimental results in the table show that when the number of neurons is 8, it could get minimum training error, and only after 131 times it reaches the target error set by the network. As a consequence, the optimal number of hidden layer's neurons is 8. Although when the number of neurons is 5 and 7, the training error is also small, they need more training steps, increasing the network's training time. In addition, with the number of hidden layer's neurons becoming larger and larger, the network training error is not smaller. For instance, when the number is over eight, the training errors increase obviously. However, too few neurons would also reduce network's classification capacity and this would also make the network lack of efficiency, such as when the number of neurons is 4, the training error gets to the maximum.

Forecast and analysis. This paper selects the former 20% of training data set as a confirmation group to verify. As to network, confirmation group is a set of known data and the specific results are shown in the Fig. 2.As we can see that structure of the well trained network is stable. The neural network's maximum absolute error of prediction period for 3 months and 6 months is 0.0047, 0.0064, respectively. Basically it is a satisfactory network structure and the network testing can go to the next step.

From Fig. 3, we can get that prediction effect is good for the three months static forecast. The CPI trend for future direction is basically consistent with the actual trend, and as to the specific month's CPI point forecast, the estimate accuracy is also high. The maximum absolute error is 0.0139, and the minimum absolute error is 0.0005. As for six months forecast, the forecast and the real value is relatively very close with the maximum absolute error not more than 0.02.

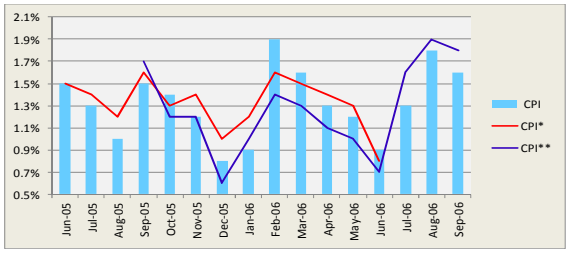

Fig. 2 Test results of BP neural network model*

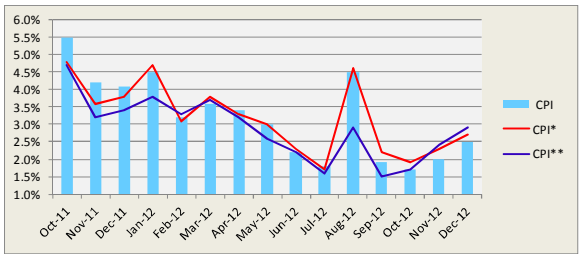

Fig. 3 Forecast value and real value trend chart *

Summary

The BP neural network as a new prediction method begins to get applied in the field of inflation forecast more and more often in recent years. This paper takes four factors into consideration, which are excess liquidity, exchange rate, inflation expectations, and macroeconomic leading index to forecast CPI and then carries out empirical test based on BP neural network model, using monthly data from March 2005 to December 2012. The model has two different forecast periods, including 3 months and 6 months, respectively. The empirical results show that forecast effect of the neural network is good and it also proves that BP neural network model is suitable for inflation forecast research.

Research on Related Model for Urban Public Crisis Handle Mechanism

Yongchang Ren

College of Information Science and Technology, Bohai University, Jinzhou, P.R. China

1213552916@qq.com

Keywords: urban management; public crisis; handle mechanism; evaluation model; prediction model; stakeholders

Abstract. China is in a critical period of urbanization, and various social contradictions continue to be accumulated, emerged and enlarged, so public crisis management mechanism has been highly valued by governments at all levels with the public crisis events are occurred frequently. The paper conducts study for the problems in the current urban public crisis handle mechanism. First, the evaluation model of crisis management can be researched, and crisis management can be divided into four stages to evaluate respectively, they are Reduction, Readiness, Response and Recovery; then, we should research crisis prediction model to strengthen prediction, prevention and monitoring of the crisis before the crisis happened; finally, stakeholders analysis model should be studied, and scientific analyzing the interests of the various stakeholders and the relationship among them. From the theoretical point of view, the paper carries on a study for crisis handle mechanism to provide support for improving the crisis handle level.

Introduction

"Public Crisis" is an abnormal state and event with high uncertainty, instability and threatening, and it can cause serious damage to lives and properties, cause widespread panic in the public psychology, disrupt normal social orders and public relations and destroy the basic social values and norms. Public crisis handle is an important area of public administration, is an organized, planned, ongoing dynamic management process, and the government must take a series of control behaviors at different stages of crisis development to effective prevent, treat and eliminate crisis for the potential or current crisis [1,2].

Our country urban public crisis handle management is still in its infancy. There are many problems in China's public crisis handle work, so it still has a long way to go, compared to the western developed countries which have a perfect crisis handle management system and mature crisis handle mechanism such as United States, Japan and Russia. The majority of our local governments' contingency response system is very immature because it just amends and supplies the original disaster management system. In addition, there are many problems in China's urban public crisis management, and there is a considerable distance between our urban public crisis management and its theoretical assumption, so the research efforts of China's urban public crisis management still need to be strengthened. The relevant model of urban public crisis handle studied in this research provides support for the management of public crisis handle and decision-making.

Crisis Management Evaluation Model

The evaluation of crisis management is an important aspect of crisis management. Evaluating the crisis events and approaches can help us identify crisis events, and it also can look for ways to prevent the crisis from happening again and improve treatment measures of response and rebuild action. Scholars at home and abroad focus on evaluation method of crisis management performance, establishment of evaluation index system, institutional construction of crisis management evaluation, crisis handle process evaluation and other aspects in crisis management evaluation.

Crisis management evaluation model studied in the paper bases on the famous 4R model which proposed by America crisis management expert Robrt Heath. Public crisis management is

composed of reduction, readiness, response, recovery, so we can take the first letter in English to become 4R model, and the structure shows in Fig. 1 [3,4]. Transverse is the four stages of the crisis evolved, and lengthwise divides the evaluation content of crisis into three factors and the evaluation content at each stage can be evaluated from these three factors.

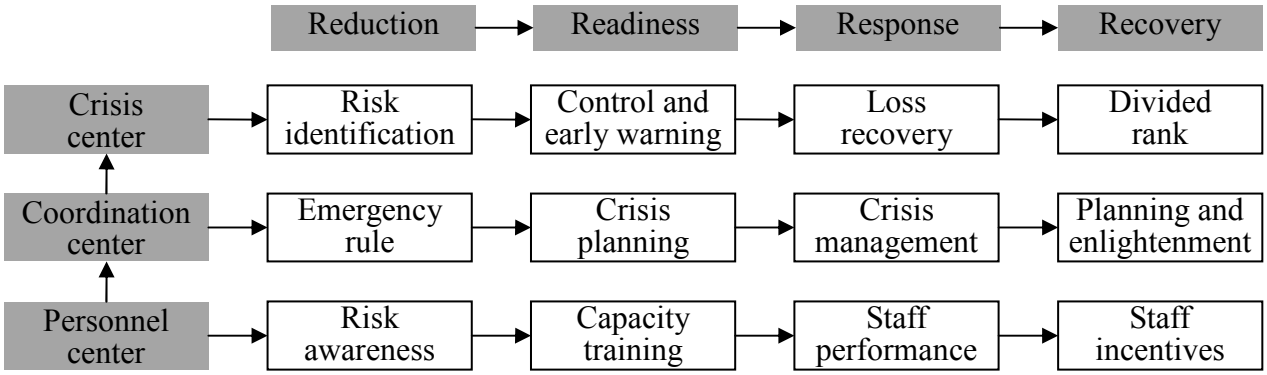

Fig. 1. Crisis management evaluation model

Four stages of the crisis evolved are illustrated as follows: Reduction is the core content of crisis management. The occurrence and impact of the crisis can be reduced by reducing risk, avoiding wasting time and diluting poor resource management; Readiness mainly conducts crisis prevention, and the relevant government departments can choose various experts, so a crisis management team is consisted to develop crisis management plans and conduct daily work of crisis management; Response, which emphasizes crisis comes, is that the relevant departments should make what kind of reaction to resolve the crisis strategically; Recovery includes two aspects, it can provide experience and support for future crisis management to avoid repeating the mistakes of history.

Three elements of evaluation content are explained as follows: Crisis center: the source of the crisis, the control of crisis and precaution system, the partition of crisis level and restoration from losses caused by the crisis belong to the scope of the crisis center; coordination center is a process which the managers make great effort to when they manage activities, deal with crisis and communicate with people; personnel center is all the personnel involved in crisis management, it includes managers, victims, bystanders and so on.

Crisis Event Prediction Model

This paper selects GM(1,1) prediction model that is based on the theory of gray, and the model is expressed as follows [5,6]:

Leting the original series is $x^{(0)}$, and the series generated by 1-AGO is $x^{(1)}$, and the differential equation model is established according to the cumulative created series as follows:

$$\frac{dx^{(1)}}{dk}+ax^{(1)}=u \tag{1}$$

The discrete form of solution is described as follows:

$$x^{(1)}(k+1)=\left(x^{(0)}(1)-\frac{u}{a}\right)e^{-ak}+\frac{u}{a} \tag{2}$$

You can get the predicted cumulative sequence according to this model to analogy when you determined the parameters *a* and *u*, and when it passed the examination, then cumulating it to get predictive value. Modeling steps are as follows:

(1) The original sequence of $x^{(0)}$ can be cumulative generated series of $x^{(1)}$ according to the following formula to calculate;

$$x^{(r)}(k)=x^{(r-1)}(1)+x^{(r-1)}(2)+\cdots+x^{(r-1)}(k)=\sum_{i=1}^{k}x^{(r-1)}(i)=x^{(r)}(k-1)+x^{(r-1)}(k) \tag{3}$$

(2) Using the least square method according to the following formula to determine the model parameters for $x^{(1)}$;

$$\hat{a} = [a \quad u]^T = \left(B^T B\right)^{-1} B^T y_N \tag{4}$$

(3) Building prediction model and calculating cumulative sequence;

$$\hat{x}^{(1)}(k+1) = \left(x^{(0)}(1) - \frac{u}{a}\right)e^{-ak} + \frac{u}{a} \tag{5}$$

(4) Conducting residual test for prediction model;

(5) The upper and the lower bounds of the predictive value should be determined according to future changes in the system, namely the gray plane can be determined according to the following formula;

upper bound: $x^{(1)}_{\max}(n+k) = x^{(1)}(n) + k\sigma_{\max}$; lower bound: $x^{(1)}_{\min}(n+k) = x^{(1)}(n) + k\sigma_{\min}$.

In the formula, it is an increased upper bound of $x^{(0)}$ when the $\sigma_{\max}$ in behind of n point; it is an increased lower bound of $x^{(0)}$ when the $\sigma_{\min}$ in behind of n point.

(6) Using the model to predict. Using accumulation to generate predictive value of series $x^{(1)}$, and using regression to restore it, so that you can get the predictive value of the original series $x^{(0)}$, such as the prediction can be completed once meet the condition of gray factor.

Stakeholders Analysis Model

At present, China's public crisis management is a critical transformation period from the traditional "vertical management" to multiple collaborative governance. This requires us to form networked multi-management structure of "transverse to the edge, vertical to the end, the layers of contact, interlocking" objectively. Elements of the structure are extremely complex, and the complexity determined its operation mechanism, at the same time, it corresponding means that it inevitably involves in governing relationship between the government and society, between citizens, between communities, between behavioral relationship of interest groups and interest relationship. Therefore it is necessary to build stakeholders analysis model of multiple interests in public crisis, and it shows in Fig. 2 [7-9].

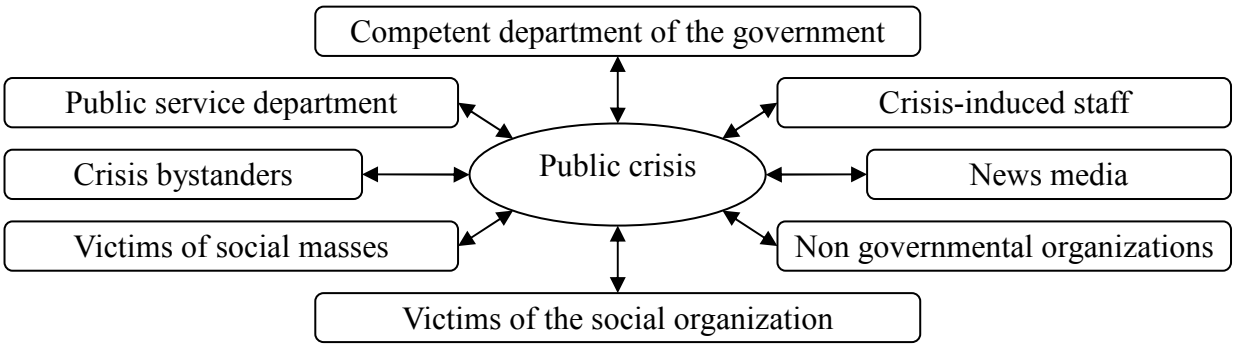

Fig. 2. Stakeholder on public crisis

As can be seen from Fig. 2, stakeholders include eight categories. Drawing on the thinking of "Mitchell score", stakeholders are classified as follows according to the relevancy, impact and urgency of stakeholders in the public crisis:

(1) Strong core stakeholders are the urgent organizations which have high relevancy and large influence in the occurrence and treatment process of public crises, and they have the responsibility and obligation to manage crisis. This kind of stakeholders mainly refer to competent government departments related to crisis and those induced by the crisis in the public crisis.

(2) Vulnerable core stakeholders are organizations or individuals with weak influence but have the urgency, and its the occurrence of the crisis is correlated to influence height, and they include

both public victims and victims of social organization. They expect to get proper rescue and remedy and recovery of interest in a public crisis.

(3) Fringe stakeholders refer to the organizations which can participate in crisis handle on account of responsibility or moral after crisis happened, and they have some relevance and influence with crisis, but the urgency is weak. They mainly include Non governmental organizations, News media and Public service department and so on.

(4) Potential stakeholders refer to some organizations and individuals with weak relevancy, urgency and impact in terms of public crisis. This type of stakeholders can grow into core stakeholders, fringe stakeholders and non stakeholders with the development trend of the public crisis, and the major potential stakeholders are bystanders of crisis in the crisis.

Conclusion

The frequent occurrence of all types of emergencies, group events, safety accidents and others have become a factor serious affecting China's urban harmony and stability, so building an effective urban public crisis handle mechanism suited for our country's condition becomes arduous task as soon as possible without delay. This paper aims to study and explore new theories and new ways of urban public crisis handle management to address the key issues of urban public crisis emergency management, so we can reduce the risk of decision-making, improve the government's ability to govern particular the ability to manage complex situations and the ability to deal with crises events. The paper can theoretically further enrich and complement existing theories and methods of urban crisis management, and it can provide scientific reference for the decision-making behavior in government crisis management in practice.

Keywords: network-centric warfare; missile and artillery air defense group; damage effectiveness

Abstract. Currently, missile and artillery air defense system under the conditions of the network has become a very important air defense weapon system, and play an unprecedented role in modern warfare process. To develop high damage performance missile and artillery air defense system has become common goal. It is necessary to study the impact of missile and artillery air defense system damage performance for improving damage probability of missile and artillery air defense system.

Introduction

In modern warfare, threats are changing constantly, destructiveness, threatening and universality of the war have constantly increased, and it makes the need for joint defense weapons systems on combat tactics, the war needed to cover the range of low, a diverse range of low altitude and high-altitude regions such as operational requirements. Currently, missile and artillery air defense system under the conditions of the network has become a very important air defense weapon system, and play an unprecedented role in modern warfare process. To develop high damage performance missile and artillery air defense system has become common goal. It is necessary to study the impact of missile and artillery air defense system damage performance for improving damage probability of missile and artillery air defense system.

Research Statuses

2.1 Network Centric Operation System Effectiveness Evaluation

"Network Centric Warfare" is a new concept of operations for the U.S. Navy to develop and adapt to the IT revolution, the new military requirements consequent proposed. It is defined as follows: through the Global Information Grid, the scattered distribution of combat elements integrated into networked battle command systems, combat forces and combat system, security system, between the various operational elements shared situational awareness, to maximize the information advantage into the decision-making and action advantages, give full play to the overall combat effectiveness [1].

With the continuous development of the U.S. Navy weaponry and combat theory, "Network Centric Warfare" goes from vision to reality. Compared with the traditional "platform-centric warfare" in the NCW C^4ISR system "combat multiplier" effect is more prominent, the impact on operations is also greater. Meanwhile, the C^4ISR system performance and operational impact assessment has become an increasingly important issue, and has important theoretical and practical significance [2].

Traditional system performance and operational effectiveness are still focused on the definition of weapons and equipment systems, which obviously do not meet information warfare or combat systems against requirements. Therefore, it is necessary to extend the concept of weapon system performance, and put forward the concept of system performance.

System performance evaluation is the highest level of effectiveness of the performance evaluation. Network Centric Operation System Effectiveness Evaluation refers to the network-centric warfare environment, assess the main measure of network-centric warfare systems carry out combat operations troops reached the actual extent of the process. It is

believed that network-centric warfare system performance assessment is to combat system to measure and evaluate the level of play.

2.2 Network Centric Operation System Effectiveness Evaluation Method

2.2.1 Analytical Method

Analytical method [3] is used to describe and solve mathematical analytical expressions number of relationships in the real world, the analytic expression results in an accurate value indicates the number of solution results. As the process of applying combat weapon system is a random process, so the mathematical basis of the analytical method used in this regard is mainly probability theory and stochastic process theory, the corresponding modeling probabilistic methods are usually resolved. Its essence is to use analytic analysis of the effects of the war, the method of random factors such functions by random factors known to calculate the probability characteristics. Specific methods are: WSEIAC (Weapon System Advisory Committee) model, queuing network theory, information theory methods and objective planning methods. Queuing network theory and information theory methods have been applied to evaluate the performance of network-centric warfare systems.

Advantage of the analytical method is the formula transparent, and easy to understand, simple to calculate, application flexibility. For some of the potential problems, such as the system of "bottleneck" subsystem performance impact of certain parameters, such as changes in the whole system, analytical method can draw a clear understanding of the law. The disadvantage is that the analytical method to establish the difficulty of mathematical models, mainly in: Category combat effectiveness evaluation system objects more widely, from the strategic to the tactical level, there are performance assessment of the different levels of the system, the mathematical application of analytical method Difficulty model is different, the higher the level the system, the more complex the system, the more complex the relationship between the index, the more difficult to establish the mathematical model; restricted even for the same system, the performance is also affected by the environment, tasks and other factors, by analytical Mathematical models have created a different method.

2.2.2 Statistical Experimental Method

Statistical experimental method [4] is known as Monte Carlo method or a computer simulation method, and it is a computer simulation of random phenomena as a tool for mathematical method. Its main features are: distributed random variables in order to obtain the number of known probability distribution of the decision of unknown random variables, generates a random number with every random variable with a known distribution of mathematical methods (that is, one of the random variable The possible values), and entered into a mathematical model of these random variables determine the unknown random variables, the calculated random number of random variables is unknown. Such independent enough times calculated the unknown random variables can be a random number; this group is called the random collection of a sample of the random variable.

Using statistical experimental method is the basic premise: You must be able to construct a specific weapon system in line with the course of affairs characterized by physical and mathematical model and has a high resolution. In addition, you must also know the known distribution pattern of random variables, the distribution density and distribution functions. Through statistical experimental method to compare the dynamic response of the actual situation realistically, and with high reliability, but there are difficulties in the accuracy of modeling complexity and model.

2.2.3 Analysis Hierarchy Process

AHP (Analytic Hierarchy Process) is proposed by T.L.Satie in 1970s [5].

AHP is a practical method for multi-criteria decision making, which embodies the basic characteristics of the analysis process decision-thinking people, that decomposition, judgment, synthesis. This method of combining its qualitative and quantitative factors to deal with the characteristics of various decision-making, as well as systems, flexible, simple and advantages in the field of complex systems to assess attention and has been widely applied. Advantages AHP is

available on a variety of weapon systems programs and mission analysis tasks, the disadvantage is difficult to describe the interactions and nonlinear relationships weapon systems and combat concepts.

Summaries

There are many ways to assess the effectiveness of Network-centric warfare system, but in this study, because of the limited equipment and related technology, only some simple, intuitive and effective methods are used for effectiveness evaluation of the missile and artillery air defense system.

Damage assessment for a single weapon platform effectiveness can be the first analytical method for detecting ability, shooting ability and the ability to damage a single weapon platform system were analyzed to obtain a single weapon combat effectiveness evaluation of the results of a comprehensive platform after; then develop simulation system using statistical experimental method for damage efficiency single weapon platform for analysis and verification.

For multi-weapon platform effectiveness of cooperative damage assessment can be integrated using the analytical method, AHP and fuzzy analysis method for multi-platform systems ability to detect weapons, shooting ability, and ultimately damage the ability to model and analyze the effectiveness of combat; then develop simulation system, in two steps, the use of experimental methods and exploratory statistical analysis methods to verify the multiple weapons platforms cooperative combat performance gain.

Keywords: integrated logistics; manufacturing; remanufacturing; fuzzy chance constrained; confidence level

Abstract: Considering the uncertainty of waste products recovery quantity in consumption areas, a fuzzy optimization model for manufacturing/remanufacturing integrated logistics network with capacity constraints was constructed to determine the number and location of the facilities, the flows between each facility. A numerical example was provided to demonstrate the feasibility of the model.

Introduction

Remanufacturing is a process that transforming the waste products into new products. The raw material is the old machinery equipment. It is a new manufacturing process using specialized technology. Due to reusing the scrap value of waste products, it can help save natural resources, reduce pollution and promote the development of circular economy. Now, it has drawn more and more countries' attention, especially the industrialized countries. For the successful implementation of remanufacturing, improving efficiency and effectiveness of logistics systems operations, many scholars studied the optimization design problem of remanufacturing logistics network[1,2,3,4,5,6,7]. And most of these studies have focused on independent construction of remanufacturing logistics network and new construction of manufacturing/remanufacturing integrated logistics network. But constructing manufacturing/remanufacturing integrated logistics network based on the original logistics network contributes to reduce the total construction cost. In addition, most remanufacturing logistics network optimization model is deterministic, stochastic programming model and fuzzy programming model are less. Based on the above studies, this paper uses fuzzy parameter to describe the uncertain recovery quantity, and constructs a fuzzy programming model for the manufacturing/remanufacturing integrated logistics network. A numerical example is provided to demonstrate the feasibility of the model.

Model Formulation

Problem Description. The manufacturing/remanufacturing integrated logistics network is composed by the consumption areas, recycling centers, remanufacturing centers, manufacturing centers, distribution centers and waste disposal points and the transportation routes between them. The integrated logistics network optimization design is to determine the quantity and location of recycling centers, remanufacturing centers, and find the suitable flows between various facilities to minimize the total cost.

Model Assumption. In order to facilitate analysis, we give the following assumptions:

(1)The recovery quantity in consumption areas is a fuzzy number;

(2)The quantities and locations of distribution centers, manufacturing centers and waste disposal points are certain;

(3)New facilities only can be established in the known candidate locations;

(4)The fixed cost, operating cost and transportation cost are certain;

(5)The recycling centers and remanufacturing centers have capacity limitation;

(6)There is a linear relationship between the transportation cost and distance.

Formulation of the Model. The notation can be represented as follows:

Indices:i: consumption area ($i = 1,2,\dots,I$);j:distribution center($j = 1,2,\dots,J$);k: manufacturing center($k = 1,2,\dots,K$);l:recycling center candidate ($l = 1,2,\dots,J,J+1,\dots,L$); m; remanufacturing center candidate($m = 1,2,\dots,K,K+1,\dots,M$); n: waste disposal points($n = 1,2,\dots,N$).

Parameters:Q_i: recovery quantity of waste products in consumption area;F_l,E_l,W_l: fixed cost, operating cost and maximum capacity of l;F_m,E_m,W_m: fixed cost, operating cost and maximum capacity of k;p:unit cost of waste products; d_{il},TC_{il}: the distance and transportation cost between i and l;d_{lm},TC_{lm}: the distance and transportation cost between l and m;d_{ln},TC_{ln}: the distance and transportation cost between l and n;d_{mj},TC_{mj}: the distance and transportation cost between m and j;d_{mn},TC_{mn}: the distance and transportation cost between $m$and n;d_{ji},TC_{ji}: the distance and transportation cost between j and i;α,β: the discard rate of waste products in distribution centers and remanufacturing centers;p: the unit cost of waste products.

Decision variables: Y_l: 1,if distribution center is opened at location l,0,otherwise;Z_m: 1,if remanufacturing center is opened at location m,0,otherwise;x_{il}: quantity of waste products shipped from i to l;x_{lm}: quantity of waste products shipped from l to m;x_{ln}: quantity of solid wastes shipped from l to n;x_{mj}: quantity of waste products shipped from m to j; x_{mn}: quantity of solid wastes shipped from m to n;x_{ji}: quantity of waste products shipped from j to i.

The problem can be formulated as follows:

$$\min Z = \sum_{l\in L} F_l Y_l + \sum_{m\in M} F_m Z_m + \sum_{i\in I}\sum_{l\in L} x_{il} TC_{il} d_{il} + \sum_{l\in L}\sum_{m\in M} x_{lm} TC_{lm} d_{lm} + \sum_{l\in L}\sum_{n\in N} x_{ln} TC_{ln} d_{ln} + \sum_{m\in M}\sum_{j\in J} x_{mj} TC_{mj} d_{mj} + \sum_{m\in M}\sum_{n\in N} x_{mn} TC_{mn} d_{mn} + \sum_{j\in J}\sum_{i\in I} x_{ji} TC_{ji} d_{ji} + E_l \sum_{i\in I}\sum_{l\in L} x_{il} + E_m \sum_{l\in l}\sum_{m\in M} x_{km} + OT\left(\sum_{l\in L}\sum_{n\in N} x_{ln} + \sum_{m\in M}\sum_{n\in N} x_{mn}\right) + p\sum_{i\in I}\widetilde{Q}_i \quad (1)$$

$$\sum_{l\in l} x_{il} = \widetilde{Q}_i \qquad \forall i \quad (2)$$

$$(1-\alpha)\times\sum_{i\in I} x_{il} = \sum_{m\in M} x_{lm} \qquad \forall l \quad (3)$$

$$\alpha\times\sum_{i\in I} x_{il} = \sum_{n\in N} x_{ln} \qquad \forall l \quad (4)$$

$$(1-\beta)\times\sum_{l\in L} x_{lm} = \sum_{m\in M} x_{mj} \qquad \forall m \quad (5)$$

$$\beta\times\sum_{l\in L} x_{lm} = \sum_{n\in N} x_{mn} \qquad \forall m \quad (6)$$

$$\sum_{m\in M} x_{mj} = \sum_{i\in I} x_{ji} \qquad \forall j \quad (7)$$

$$\sum_{i\in I} x_{il} \le Y_l W_l \qquad \forall l \quad (8)$$

$$\sum_{l\in L} x_{lm} \le Z_m W_m \qquad \forall m \quad (9)$$

$$Y_l, Z_m \in \{0,1\} \qquad \forall l,m \quad (10)$$

$$x_{il}, x_{lm}, x_{ln}, x_{mj}, x_{mn}, x_{ji} \ge 0 \qquad \forall i,j,k,l,m \quad (11)$$

The objective function (1) tries to maximize the profit after removing the total cost. Constraint (2) requires the total outgoing flows from each consumption area should be the same as the waste products recovery quantity. Constraints (3) and (4) are the balance equations to ensure the quantities that enter to recycling centers must be equal to the quantities that leave them. Constraint (5) and (6) ensure reusable components would be shipped to remanufacturing centers, and the rest would be transported to waste disposal points. Constraint (7) ensures the total outgoing flows from

remanufacturing center should be equal to the quantities that leave them. Constraint (8) and (9) are the maximum capacity limitation for recycling centers, remanufacturing centers, respectively. Constraint (10) represents the binary variables. Lastly constraint (11) enforces the non-negativity restriction on the decision variables.

Solution method for the model

In order to solve the model, the fuzzy parameter should be clarified. Based on the study of Liu and Iwamura [6,7], the model can be transformed to the following mixed integer programming model.

$$\min f \tag{12}$$

$$\sum_{l\in L} F_l Y_l + \sum_{m\in M} F_m Z_m + \sum_{i\in I}\sum_{l\in L} x_{il} TC_{il} d_{il} + \sum_{l\in L}\sum_{m\in M} x_{lm} TC_{lm} d_{lm} + \sum_{l\in L}\sum_{n\in N} x_{ln} TC_{ln} d_{ln} + \sum_{m\in M}\sum_{j\in J} x_{mj} TC_{mj} d_{mj} + \sum_{m\in M}\sum_{n\in N} x_{mn} TC_{mn} d_{mn} + \sum_{j\in J}\sum_{i\in I} x_{ji} TC_{ji} d_{ji} + E_l \sum_{i\in I}\sum_{l\in L} x_{il} + E_m \sum_{l\in l}\sum_{m\in M} x_{km} + OT\left(\sum_{l\in L}\sum_{n\in N} x_{ln} + \sum_{m\in M}\sum_{n\in N} x_{mn}\right) + p\sum_{i\in I}(1-\theta)Q_{i3} + \theta Q_{i2} \le f \tag{13}$$

$$\sum_{l\in l} x_{il} \ge (1-\theta)Q_{i1} + \theta Q_{i2} \qquad \forall i \tag{14}$$

$$\sum_{l\in l} x_{il} \le (1-\theta)Q_{i3} + \theta Q_{i2} \qquad \forall i \tag{15}$$

Other constraints are the same as the constraints from (3) to (11), where $\theta(0 \le \theta \le 1)$ is a given confidence level. So the model has been converted to a deterministic model. And it can be solved by commercial software CPLEX, LINDO, LINGO, and so on.

Numerical Example

A manufacturing/remanufacturing integrated logistics network needs to be constructed. The recovery quantity is fuzzy parameter. p=800RMB/t, $TC_{ij}=TC_{jk}=TC_{kl}=TC_{km}$=6RMB/(t·km), θ=0.9. Other parameters are shown from table 1 to table 5.

Tab.1 Recovery quantity in consumption areas (t)

	Quantity		Quantity		Quantity		Quantity
I1	(25,27,37)	I2	(31,34,36)	I3	(42,45,49)	I4	(18,19,22)
I5	(22,24,27)	I6	(19,22,24)	I7	(27,29,33)	I8	(33,34,38)
I9	(22,26,31)	I10	(17,21,25)				

Tab.2 Distance between potential recycling centers and consumption areas, potential remanufacturing centers (km)

		Consumption areas										Remanufacturing centers

Tab.4 Distance between potential remanufacturing centers and distribution centers (km)

		Remanufacturing centers					
		1	2	3	4	5	6
Distribution centers	1	31	22	17	22	35	17
	2	24	19	14	29	32	42
	3	27	34	25	31	16	18

Tab.5 Maximum capacity, fixed cost and operating cost of potential recycling centers and remanufacturing centers

	Storage centers						Dismantling centers					
	1	2	3	4	5	6	1	2	3	4	5	6
Maximum capacity (t)	100	100	100	100	100	100	100	100	100	100	100	100
Fixed cost (RMB)	650000	650000	650000	900000	900000	900000	3250000	3250000	4760000	4760000	4760000	4760000
Operating cost	1750	1750	1750	1750	1750	1750	5500	5500	5500	5500	5500	5500

Having the above parameters, the model can be solved by LINGO11.0. The optimal solution of structure variables is given in table 6. The optimal total cost is 17513210 RMB. We build recycling center at $L1$, $L2$ and $L3$, remanufacturing center at $M1$, $M2$ and $M5$.

Tab.6 Optimal solution of structure variables

Y_1	Y_2	Y_3	Z_1	Z_2	Z_5	Others
1	1	1	1	1	1	0

Conclusions

This paper studies the optimal strategy of manufacturing/remanufacturing integrated logistics network when the recovery quantity is fuzzy number, and constructs a fuzzy programming model for it. Finally, an example is given to demonstrate the feasibility of the model. And the multi-objective situation should be studied further in the future.

Keywords: Crop, Growth, Management, Model

Abstract. In order to explore the growth mechanism of crop, further improve the level of crop growth management, the simulation research technology for management model of the crop growth is proposed, meanwhile ontology and visual model technology are used in the establishment process of crop growth model, so all kinds of states of crop growth at different stages can be predicted, then efficiency of crop growth management is greatly improved. The research on the crop growth model has important theory and practical significance in understanding the yield of the various parts of the crop, and help the manager understand the growth discipline of crop.

Introduction

The development of crop growth management model will make full use of information management, dynamic simulation, virtual reality, knowledge engineering, precise control and other modern information technologies[1], and the information and digital technology in production factors and production process of crop are regarded as main research targets, and we develop information management of crop growth and resources management, the digital simulation of crop growth management process, crop growth management knowledge expression modeling, visual design of key technologies in crop growth management and so on, further study the hardware and software technology of crop growth management development, then achieve digital control, high precision, visualization, and network of prediction of crop growth management model[2].

Key Technologies

Agricultural Ontology. Agricultural ontology is to use the computer language to regulate the concept expression of agricultural knowledge, which is the scientific methodology that implements knowledge services and agricultural origination. The exchange, reusing and sharing of information and knowledge have become an urgent task of computer technology. For knowledge engineer, natural language processing, information retrieval system, intelligent information integration and knowledge management, information exchange and software technology and other fields, the ontology is more than the database of information that can enrich in the lexical and semantic, and it is not just structure of data storage, but can provide a wealth of rigorous theory and describe moving and changing of things or concepts, so the ontology is the foundation of description of entities, attributes, processing and relationship. This formal description can become the sharing and reusable components of software system, which can achieve interoperability and inheritance between different systems, so basic structure is provided for the construction of knowledge base.

Classification and relation of characteristic words that are formed in the agricultural ontology are used to carry on the confirmation of uneven husband law, and form relatively discipline branch data dictionary which is composed of the finite character words, namely is the optimization of data dictionary. The retrieval word that is provided by user is used to match data dictionary, and strategy is used to analyze the results of matching to determine the subject of the information and index. The classification system of agricultural information network is made, indexing information is used to classify information. Computer programming is used to realize automatic classification and indexing of agricultural information network.

Growth Model. Virtual reality technology is the second generation of multimedia technology which is after the man-machine system interface technology, which combines a variety of the latest achievements of science and technology such as computer graphics technology, computer simulation technology, sensor technology, display technology, the three-dimensional graphical environment and their interactions are created as a true reflection of the simulation. The main characters of virtual reality technology system are as shown: a perception of visual, hearing, touch, smell, taste and other information; and allows users to temporarily escape from the external environment and integrated with virtual world. Visualization in scientific computing is to explore computing and data, and gain understanding and insight into the data. The goal is to test the numerical or large amounts of data obtained in accordance with its own combination of physical background, and show the relationship between the content and performance with the way the image data, so it is easy to grasp the overall evolution of the process and find its inherent laws, improve rich scientific way and shorten the research cycle.

Three-dimensional digital technology regards the computer as the core, and achieves accurate collection object space coordinates based on acoustic, optical, magnetic and other principles of development. The crops that can describe the morphology of the feature points are selected, then obtain three-dimensional coordinate system in the coordinates, so we can easily calculate the branching angle and azimuth, blade geometry and so on. Three-dimensional digital technology can achieve the continuous, accurate monitoring for the process of crop growth morphology, then determine its own rules. Now three-dimensional digital technologies based on laser, micro-radar technology have also been made, if these methods become mature, it will be able to achieve more rapid plant morphology, accurate, non-contact monitoring.

Database of Crop Growth Management Resource. The crop growth management resource database supports the query from the crop growth model and connects with the existing data to calculate the new data, which are used to predict or update data. The crop growth management resources database management system includes the management and maintenance functions of the resource base of crop growth management, then including crop growth and management of resources survey data searching, data management, system maintenance and so on. In order to meet the growth of agricultural crops, the management parameters of various crops growth not only timely understand and grasp, but also summarize the laws of crop growth and the requirements of the various parameters[5], the crop growth management resource database can give crops growth and management of resources real-time and the display of historical data table and the curve of real-time trend curves and historical trends, which can ensure that users can look at real-time resource parameters of the crop growth of the current value and trend curve[6].

Knowledge Ontology of Crop Growth Management. Ontology provides the shared conceptualization specification for crop growth model, this specification is described based on a kind of formal way, so that users and computers can share and reuse domain knowledge in a structured way. The ontology can clarify the structure of knowledge, the ontology elements such as concept, properties, functions, axioms and instances of domain-specific are used to describe knowledge and framework, ontology reuse can avoid repetitive domain knowledge, and unified terminology and concepts make it possible for knowledge sharing.

According to the definition of the ontology, the resources information ontology of crop growth management are defined as the conceptual models which the crop growth management resource domain involve, and consensus can be made in resource management of crop growth management field, and are expressed in computer, and provides resource decision domain sharing of crop growth management. The crop growth management resource information ontology consists of the concept, properties, axioms, instances, the crop growth management resource decision-making concept refers to the collection of involved nouns in the process of crop growth management resources business, the domains are for crop growth management resource areas, including the collection of the crop growth management resources and operational decision making.

Establishment of Crop Growth Model

The establishment of crop growth model requires the following steps:

The conditions of crop growth are shown at the different stages of crop growth and under different environmental factors, we can judge growth mode of branch, the type of scores, then determine the overall framework to describe the crop morphology.

The combination of the morphogenetic model and specific physiological and ecological model are made, which are based on biomass production and distribution in different organs at each stage, and calculate the growth and development state of crops in various stages of growth.

Based on the geometric dimensions and spatial position of the various growth stages which are calculated for each crop organs, the visual model structure is used to build three-dimensional crop graphics; The computer graphics technology such as texture mapping and light calculation, the depth of blanking anti-aliasing, projection and so on are used to deal with crops in three-dimensional geometric structure to generate a realistic image of the crops graphics.

Implementation and Test of Model

Composition of Module. The model system consists of the model management module, knowledge management module, inference engine, database management module, and model base, knowledge base, and human-computer interaction interface.Growth model of plant uses Visual C++ and three-dimensional drawing tool OpenGL. OpenGL is three-dimensional computer graphics software interface which is suitable for a variety of hardware platforms and operating systems. Currently it has become internationally recognized as the industry standard and open three-dimensional graphics, and is widely used. In order to verify the validity and correctness of the system, several modules of the system are tested. The results show that the comprehensive integration of expert system knowledge model and virtual growth model achieve complement of different levels of knowledge granularity reasoning of expert system. The cultivation management recommendations which quantitative analysis is based on model and expert heuristic knowledge are not only more scientific, but also are close to reality, which can guide the production.

Data Acquisition and Management of Crop. Data acquisition is the beginning of growth models of crops. Simulation of crops need large amount of data to determine the parameters. Data collection in building knowledge of crop is particularly important. In the methods of data collection, three-dimensional digital technology is developed to combine the traditional method of measuring crop with the information processing method, the use of computer graphics, image processing, pattern recognition and stereo vision and other methods quickly and accurately obtain the required information, such as access to the crops in three-dimensional coordinates of each component in the coordinate values, and further analysis of branching angle and azimuth, blade geometry and so on, on the other hand, the current system data of different types and formats vary widely, and the integration of these data management is very important to us, and the full share and application are important issues. These standards are made to establish the sharing mechanism of data.

Data Test. The test of model is to verify the suitable degree of simulation results and actual results, and check whether the model is applied in different environments by root mean square deviation between the observations and simulation values, the statistical agreement between simulation results and observations analysis and the relationship between the histogram are used to visually show agreement and reliability of analog respectively, it is said that the number of samples, the analog value, the value of the observations are much less, the prediction accuracy of the higher values and observed values of the average error are very good, then the consistency of simulation and actual values are very good, which indicate that the simulation results are generally greater than the analog value, and the actual deviation of simulated poor model will run in a simulated environment and is validated. After validation we can understand the simulation results are close to the real approximation of the model, thus confirming the correctness of the tolerance range.

Conclusion

Crop growth management simulation models have strong functions of system integration and dynamic prediction, the parameters of the model are required for high precision, poor operation, but also are difficult to direct the production system management decisions. System analysis methods and crop modeling techniques are used in knowledge expression system for crop growth, and it is expected to have both the advantages of crop simulation models and expert systems, and achieve the integration and coordination of dynamic prediction and management decision-making, so as to lay the foundation for the accurate and digitization of growth management of crop.

Keywords: logistics center location; fuzzy comprehensive evaluation ;factors

Abstract. Logistics center address selection is logistics system of strategic investment decision-making problem, the whole site whether reasonable logistic system has important implications. According to the principle of modern logistics center location affect the location of the factor analysis, through the system of fuzzy comprehensive evaluation method of center location mathematical model, and taking a regional logistics center location for example was introduced in detail.

Introduction

Fuzzy mathematics is a new branch of the fuzzy mathematics using the method of mathematics research and treatment of the phenomenon. Fuzzy mathematics the mainstream of development is in its application. Due to the concept of fuzzy have found a fuzzy sets, people use the description of the way the concept, evaluation, reasoning, and judge the process of decision-making and control can also use the fuzzy mathematics method to describe. For example the fuzzy clustering analysis and fuzzy comprehensive evaluation, fuzzy decision, fuzzy control, etc. These methods constitute a kind of fuzziness system theory, constitute a kind of speculative the prototype of the mathematics, it has in medical, weather, psychological and economic management, oil, geology, environment, biology, agriculture, forestry, chemical industry, language, control, remote sensing, education, sports and has a specific research results. This article utilizes the fuzzy mathematical evaluation method, the impact of the location of the logistics center the various factors on the overall system analysis, the method of qualitative and quantitative methods, organic combine for logistics center to provide the theoretical basis for siting. In this, combined with a region logistics center address selected cases, introduces fuzzy comprehensive evaluation method in logistics center location of application.

Logistics center location

Combined with a regional logistics center address selected case, the comparative method of logistics center location. Details of the alternatively, factors according to the logistics center location are rough screening, in the city's primary 4 optionally, respectively for 1 to 4. The comprehensive assessment of the optionally. In view of many factors to consider the project selection process, the application of the relevant theory of fuzzy evaluation method, qualitative analysis quantitative comparison method. According to the actual situation of logistics centers in the region, public facilities, social benefits, traffic condition, natural environment, several factors considered in selection scheme evaluation, establish the criteria, then determine the weight, expert scoring, the higher the score, the higher degree of satisfaction (near, the score may be the same), the proposed scheme according to the total number. To effectively divide the factors to influence the location of logistics center, the main influence factors can be divided into factors influencing the next level. Specific details are shown in table 1:

Table1 Logistics center location index system

The first level index	Second level index
The natural environment factor (U1)	Meteorological conditions (U11) Geological conditions (U12) Hydrological conditions (U13) Terrain conditions (U14)
Social benefits (U2)	Influence on city planning (U21) Influence of environmental protection (U22) The impact on regional economic development (U23)
Traffic conditions (U3)	Cohesion and the degree of city traffic network (U31) Relationship with the main flow of goods (U32)
Public facilities (U4)	The power and energy supply (U41) The communication status (U42)

Logistics center site selection index system is established

In combination with an area of the logistics center address selection case, this paper introduces the location of the logistics center comparison method. The optional to detailed introduction of the above logistics center, the location of the influence factors of the rough screening, the city's primary in four pieces of optional, make up respectively for 1 to 4. According to the actual situation of the regional logistics center, in for locating plan into consideration on evaluation of public facilities condition, social benefits, traffic condition, natural environment, set up several factors of each factors evaluation standard, respectively, determining the weight again, the expert scoring score the most high, the higher the level of satisfaction with the approaching, the same), and the last score can be made according to put forward the suggestion that plan. Through the influence factors on the location of the logistics center, and the effective divided the main influence factors and fine as the next level factors. One class index including：the natural environment factors (U1); Social benefits (U2); Traffic conditions (U3); Public facilities condition (U4), Secondary indexes including: Weather conditions (U11)
Geological conditions (U12),Hydrological conditions (U13),Terrain conditions (U14),The influence of the layout of the city planning (U21),The influence of environmental protection (U22),The influence on the region economy development (U23),And urban transportation network connection degree (U31),And the main flow of goods relations (U32),Power and energy supply (U41),Communication status (U42).
A region that are ready to build a logistics center, there are four candidates address to choose from, the evaluation index factor set to collect U, can be divided into the second floor. The first layer: U ={U1，U2，U3，U4}；The second floor: U1 ={U11，U12，U13，U14}；U2 ={U21，U22，U23}；U3 ={U31，U32}；U4 ={U41，U42}，Four candidates address that is prepared to choose sets V；V =(V1,V2,V3,V4)。

The fuzzy comprehensive evaluation in the logistics center location of application

In the multi-level fuzzy comprehensive evaluation model, due to the low level of factor is the level of fine factors on a stroke, weight coefficient of the size of the corresponding targets representatives in multi objective optimization of the importance of the problem, said in the important, conversely, the smaller the less important. Through the investigation and analysis of various factors, the corresponding evaluation 4 candidate address value, after data processing by fuzzy comprehensive evaluation are shown in table 2:

Table2 The Fuzzy Comprehensive Gudgement of some area

Influencing factors	1	2	3	4
Meteorological conditions	0.2	0.5	0.3	0.0
Address terms	0.1	0.3	0.5	0.1
Hydrological conditions	0.0	0.4	0.5	0.1
Topographic condition	0.0	0.1	0.6	0.3
Influence on city planning layout	0.5	0.3	0.2	0.0
Impact on environment protection	0.6	0.2	0.1	0.1

The impact on regional economic development	0.2	0. 2	0.3	0.3
Cohesion and the degree of city traffic network	0.1	0.4	0.3	0.2
Relationship with the mainflow of goods	0.3	0.4	0.1	0.2
The power and energy supply	0.1	0. 1	0.5	0. 3
Communication status	0.3	0.0	0.5	0. 2

Through the investigation and analysis of the four candidates address the various factors, the corresponding evaluation value will be after data processing by fuzzy comprehensive evaluation. In this article, the assumption experts consultation method to determine the weight, please 10 professionals to influence the logistics center respectively the location of the various factors of evaluation, take again average, the results are as follows: A1 ={0.3，0.1，0.4，0.2 }；A2 ={0.4, 0.1, 0.5}；A3 ={0.4, 0.6}；A4 ={0.3, 0.7}；A ={0.2，0.25，0.15，0.1 }；Through the fuzzy evaluation for comprehensive evaluation matrix R, composite operation B = A o R can get comprehensive evaluation result, secondary factors to judge: Ui (I =1,2,3,4), U1 ={ U11，U12，U13，U14}；The weight is：A1 ={0.3，0.1，0.4，0.2 }。To U11, U12, U13 U14, the fuzzy evaluation of a single factor judgment matrix: $R_1=\begin{bmatrix}0.2 & 0.5 & 0.3 & 0.0\\0.1 & 0.3 & 0.5 & 0.1\\0.0 & 0.4 & 0.5 & 0.1\\0.0 & 0.1 & 0.6 & 0.3\end{bmatrix}$ With operator M (∧, ∨), calculated the following level comprehensive evaluation:

$B_1=A_1 \circ R_1=\{0.3,0.4,0.1,0.2\} \circ \begin{bmatrix}0.2 & 0.5 & 0.3 & 0.0\\0.1 & 0.3 & 0.5 & 0.1\\0.0 & 0.4 & 0.5 & 0.1\\0.0 & 0.1 & 0.6 & 0.3\end{bmatrix}=\{0.2，0.4，0.4，0.2\}$；Similarly, U2 = {U21, U22, U23}, the weight is: A2 = {0.4, 0.1, 0.5} To U22 U23, the U21 international, a fuzzy evaluation of single factor judgment matrix: $R_2=\begin{bmatrix}0.5 & 0.3 & 0.2 & 0.0\\0.6 & 0.2 & 0.1 & 0.1\\0.2 & 0.2 & 0.3 & 0.3\end{bmatrix}$ Make level 1 comprehensive evaluation: $B_2=A_2 \circ R_2=\{0.4,0.1,0.5\} \circ \begin{bmatrix}0.5 & 0.3 & 0.2 & 0.0\\0.6 & 0.2 & 0.1 & 0.1\\0.2 & 0.2 & 0.3 & 0.3\end{bmatrix}=\{0.4，0.3，0.3，0.3\}$；

$U_3=\{ U_{31}, U_{32}\}$， The weight is: the A3 = {0.4, 0.6}, To U31 U32, the fuzzy evaluation of a single factor judgment matrix: $R_3=\begin{bmatrix}0.1 & 0.4 & 0.3 & 0.2\\0.3 & 0.4 & 0.1 & 0.2\end{bmatrix}$， Make level 1 comprehensive evaluation: $B_3=A_3 \circ R_3 =\{0.4，0.6\} \circ \begin{bmatrix}0.1 & 0.4 & 0.3 & 0.2\\0.3 & 0.4 & 0.1 & 0.2\end{bmatrix}=\{0.3，0.4，0.3，0.2\}$；

$U_4=\{ U_{41}, U_{42}\}$， The weight is: $A_4=\{0.3, 0.7\}$， To U41 U42, the fuzzy evaluation of a single factor judgment matrix: $R_4=\begin{bmatrix}0.1 & 0.1 & 0.5 & 0.3\\0.3 & 0.0 & 0.5 & 0.2\end{bmatrix}$ Make level 1 comprehensive evaluation: $B_4=A_4 \circ R_4 =\{0.3，0.7\} \circ \begin{bmatrix}0.1 & 0.1 & 0.5 & 0.3\\0.3 & 0.0 & 0.5 & 0.2\end{bmatrix}=\{0.3，0.1，0.5，0.3\}$

In primary factors of the comprehensive evaluation The known U = {U1, U2, U3, U4}, the weight A = {0.2, 0.25, 0.15, 0.1}, Total factor judgment matrix for: $R=\begin{bmatrix}B_1\\B_2\\B_3\\B_4\end{bmatrix}=\begin{bmatrix}0.2 & 0.4 & 0.4 & 0.2\\0.4 & 0.3 & 0.3 & 0.3\\0.3 & 0.4 & 0.3 & 0.2\\0.3 & 0.1 & 0.5 & 0.3\end{bmatrix}$,
Make level 2 comprehensive evaluation:

$$B = A \circ R = \{0.2,\ 0.25,\ 0.15,\ 0.1\} \circ \begin{bmatrix} 0.2 & 0.4 & 0.4 & 0.2 \\ 0.4 & 0.3 & 0.3 & 0.3 \\ 0.3 & 0.4 & 0.3 & 0.2 \\ 0.3 & 0.1 & 0.5 & 0.3 \end{bmatrix} = \{0.25,\ 0.4,\ 0.4,\ 0.25\}$$

To sum up, optional ground of the comparison results, was the result does not show very significant difference, so 4 piece all the region logistics center as the optional. But according to the high score, the satisfaction degree is higher (approximates to the same score, can be the principle of first selection, the project team suggest no. 2, 3 (2, 3), and then tied for land is no. 1, no. 4 (1, 4 and tied for).

Conclusion

The article introduces fuzzy comprehensive evaluation method, based on the modern logistics location principle, to affect the location of the center of each factors in comprehensive evaluation, and finally determined the optimal program, this method to make up for the rely on quantitative analysis and qualitative analysis of the shortcomings, to simple and effective help policymakers to choose the most suitable location, at the same time, the fuzzy comprehensive evaluation method also has certain inadequacies, such as logistics center of the location of the influence factors, including a score some uncertainty factors, and fuzzy mathematics this quite new mathematical method and thought method, remains to be perfect, but its application prospect but are very wide.

Keywords: merging unit, performance evaluation, triangular fuzzy number, weight, fuzzy comprehensive evaluation.

Abstract. According to the deficient situation of study in merging unit performance evaluation, this paper set up a comprehensive evaluation model for merging unit performance evaluation. Introduced triangular fuzzy number and determined the index weight through certain processing conversion, and set up a scientific system of performance indicators, and then selected normal distribution as the membership function. On this basis, this paper established a hierarchical and sub-aims comprehensive evaluation model. Finally, the model was applied for evaluating a merging unit performance. The evaluation result showed that the weight was effective and the fuzzy comprehensive evaluation model was simple and reliable.

Introduction

Intelligent substation is an important part of smart grid, and can be divided into process layer, spacer layer and Stand accused layer. The typical protecting device within process layer are intelligent terminal and merging units, which mainly collect switch and analog variables from primary equipment, then send control command, and has other functions. With the application of electronic transformer, merging unit as part of the electronic transformer takes on the important work for digital transmission of intelligent substation model, and also takes some corresponding work, such as synchronization and integral algorithm [1-2]. In the process of advancing intelligent substation, merging unit often cooperates with the traditional transformer in the form of independent equipment, merging and syncing the three-phase electric parameters from sensor module, then providing the digital signals processed for spacer layer devices.

The key mission of merging unit is to keep multiple inputs time synchronization in a short time, and forward organized data to protection and control devices. Due to the high delay and synchronization requirements of protection device in data processing, the time performance and other related performance indicators of merging unit also get attention accordingly. The performance of merging unit has been studied by many scholars [3-7], which provides a guidance for improving the performance of merging unit. But these studies mainly focused on the performance test methods and project, and the research of merging unit overall performance comprehensive evaluation method is less. Establishing a comprehensive evaluation model to evaluate the merging unit performance, can provide a scientific reference and basis for equipment selection, grasping the equipment operation condition and equipment failure analysis, and has a great significance for further construction and operation of intelligent substation.

In this paper, according to the research of the comprehensive evaluation theory, model and related technologies and methods, we introduce the triangular fuzzy number to determine index weight aiming at the index weight, at the same time set up a scientific system of merging unit performance index, which is used to realize the fuzzy comprehensive evaluation of merging unit and make the evaluation results more reasonable and scientific.

Triangular Fuzzy Number

Make fuzzy number $a=(l,\ m,\ u)$ as the triangular fuzzy number. Among them, *I*, *m* and *u* are real numbers, and meet $0\le l\le m\le u$; *m* is the principal value of triangular fuzzy number *a*; *I* is the lower bound and *u* is the upper bound; $(u-l)$ is ambiguity, showing the possible scope of values the experts giving. The fuzzy being greater, *a* is more ambiguous. When $l=m=u$, *a* become a real number in the common sense.

For any two fuzzy numbers $a_1=\ (l_1,\ m_1,\ u_1)$ and $a_2=\ (l_2,\ m_2,\ u_2)$, they has the following algorithm:

$$(1)\ a_1\oplus a_2=(l_1+l_2,\ \ m_1+m_2,\ \ u_1+u_2)$$

$$(2)\ a_1\otimes a_2=(l_1\times l_2,\ \ m_1\times m_2,\ \ u_1\times u_2)$$

$$(3)\ \lambda\otimes a_1=(\lambda\times l_1,\ \ \lambda\times m_1,\ \ \lambda\times u_1)$$

$$(4)\ (a_1)^{-1}=(1/u_1,\ \ 1/m_1,\ \ 1/l_1)$$

The Weight Based on the Triangular Fuzzy Number

If there are too many evaluation indexes in the same level, experts' judgment on the relative weights for each indicator will be difficult. The importance of merging unit performance indexes is estimated roughly by the expert, so it has a certain ambiguity. The triangular fuzzy number [9] can convert this uncertainty expression to the form of numerical value, which will be a good solution to solve the problem that it's difficult to accurately measure the relative importance degree of evaluation indexs. This article selects triangular fuzzy Analytic Hierarchy Process(AHP) [10] to calculate the weight of indicators. The concrete application steps are as follows.

1) Construct the fuzzy judgment matrix. All evaluation indexes are compared in pairs by experts, and construct fuzzy judgment matrix by using triangular fuzzy number. Note it as:

$$A=\left(a_{ij}\right)_{n\times n},\quad a_{ji}=a_{ij}^{-1} \tag{1}$$

where $a_{ij}=\left(l_{ij},\ m_{ij},\ u_{ij}\right)$, which is the degree of importance of the ith evaluation index compared with the *jth* index; m_{ij} is scale value when comparing in pairs with Analytic Hierarchy Process (AHP). The five scale is shown in Table 1.

Table 1. Scale

Comparison of importance	a_{ij}
u_i is as important as u_j	(1, 1, 1)
u_i is slightly more important than u_j	(1, 1.5, 2)
u_i is more important than u_j	(1.25, 1.5, 2)
u_i is much more important than u_j	(1.25, 1.5, 2.5)
u_i is extremely important than u_j	(1.5, 2, 2.5)

Make $m_{ij}-l_{ij}=u_{ij}-m_{ij}=\delta$, where δ is constant, and take $1/2<\delta<1$. When there are *K* experts to evaluate, a_{ij} is the comprehensive triangular fuzzy number and the computation formula is following.

$$a_{ij}=\frac{a_{ij}^1+a_{ij}^2+\cdots+a_{ij}^k}{K} \tag{2}$$

where $k = 1, 2,\ldots,K$; a_{ij}^k is the triangular fuzzy function given by the kth experts.

2）Calculate the comprehensive importance degree of every evaluation index

$$S_i=\sum_{j=1}^{n}a_{ij}\otimes\left[\sum_{i=1}^{n}\sum_{j=1}^{n}a_{ij}\right]^{-1}=\left(\sum_{j=1}^{n}l_{ij},\sum_{j=1}^{n}m_{ij},\sum_{j=1}^{n}u_{ij}\right)\otimes\left(\sum_{i=1}^{n}\sum_{j=1}^{n}l_{ij},\sum_{i=1}^{n}\sum_{j=1}^{n}m_{ij},\sum_{i=1}^{n}\sum_{j=1}^{n}u_{ij}\right)^{-1}$$

$$\approx\left(\frac{\sum_{j=1}^{n}l_{ij}}{\sum_{i=1}^{n}\sum_{j=1}^{n}u_{ij}},\frac{\sum_{j=1}^{n}m_{ij}}{\sum_{i=1}^{n}\sum_{j=1}^{n}m_{ij}},\frac{\sum_{j=1}^{n}u_{ij}}{\sum_{i=1}^{n}\sum_{j=1}^{n}l_{ij}}\right) \tag{3}$$

where S_i is the degree of comprehensive importance of the *iith* evaluation index compared with the other indexes within the fuzzy judgment matrix.

3）Calculate the possibility of being more important than , calculation formula is as follows.

$$V(S_i \geq S_j) = \begin{cases} 1 & (m_i \geq m_j) \\ \dfrac{l_j - u_i}{(m_i - u_i) - (m_j - l_j)} & (m_i < m_j, l_j < u_i) \\ 0 & \text{others} \end{cases} \quad (4)$$

where $j = 1, 2, \ldots, n; j \neq i$.

4）Calculate the weight of every index

$$W' = (d_1, d_2, \cdots, d_n);\ d_i = \min_{j=1,2,\ldots,n;\ j \neq i} V(S_i \geq S_j) \quad (5)$$

Get the weight W after unitary:

$$W = (w_1, w_2, \cdots, w_n)$$

The Fuzzy Comprehensive Evaluation Method

Merging unit performance evaluation is a multi-index comprehensive evaluation problem. For qualitative indexes through quantifying or some quantitative indexes, it is uncertain that the evaluatation result belongs to a certain hierarchy. The fuzzy comprehensive evaluation method makes full use of the fuzzy relation between evaluation index and membership grade, and makes comprehensive evaluation from various angles, so it is a kind of comprehensive decision method matching people's critical thinking. This method divides the change interval of the merging unit performance index, and makes analysis about merging unit performance indexes more deeply and objectively. Figure 1 is shown the evaluating process of fuzzy comprehensive evaluation method.

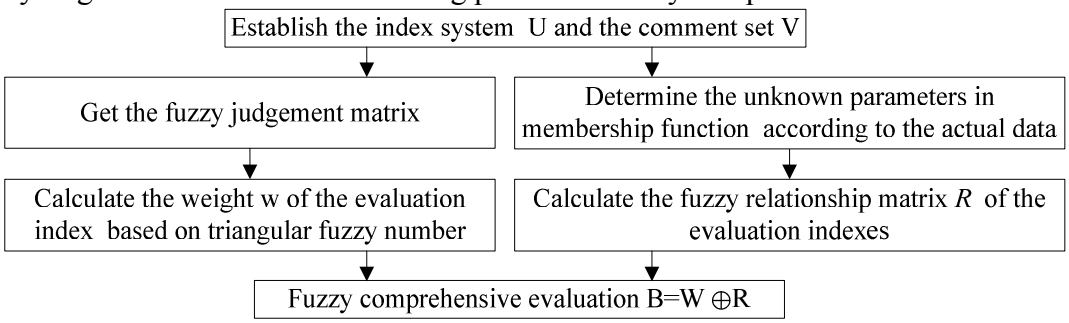

Figure 1. Fuzzy comprehensive evaluation method based on the triangular fuzzy number

Evaluation Index

Data information used by protection principle should be at the same time. When the data information from different merging units converges to one protection, it will cause protect out and even endanger grid security if the delay between each data is too big. So we must accurately grasp the merging unit performance in terms of time. With Intelligent substation being more networked, merging unit should be able to adapt to correspond through the network, and ensure data integrity in the communication. Data collection is an important function of merging unit, and it is very important for the grasp of the data accuracy. Not only accurately grasp the normal data, but also monitor the changes of emergency data in time. So we shall have corresponding indexes to measure the steady-state performance and dynamic performance.

In order to achieve the goal of intelligent substation merging unit performance evaluation, the target is divided into four points to evaluate, as shown in Figure 2.

According to the experiences and opinions of experts, merging unit performance evaluation result should be divided into three kinds of levels: optimal, good and general. So the comment set of comprehensive evaluation is $V = (v_1, v_2, v_3)$.

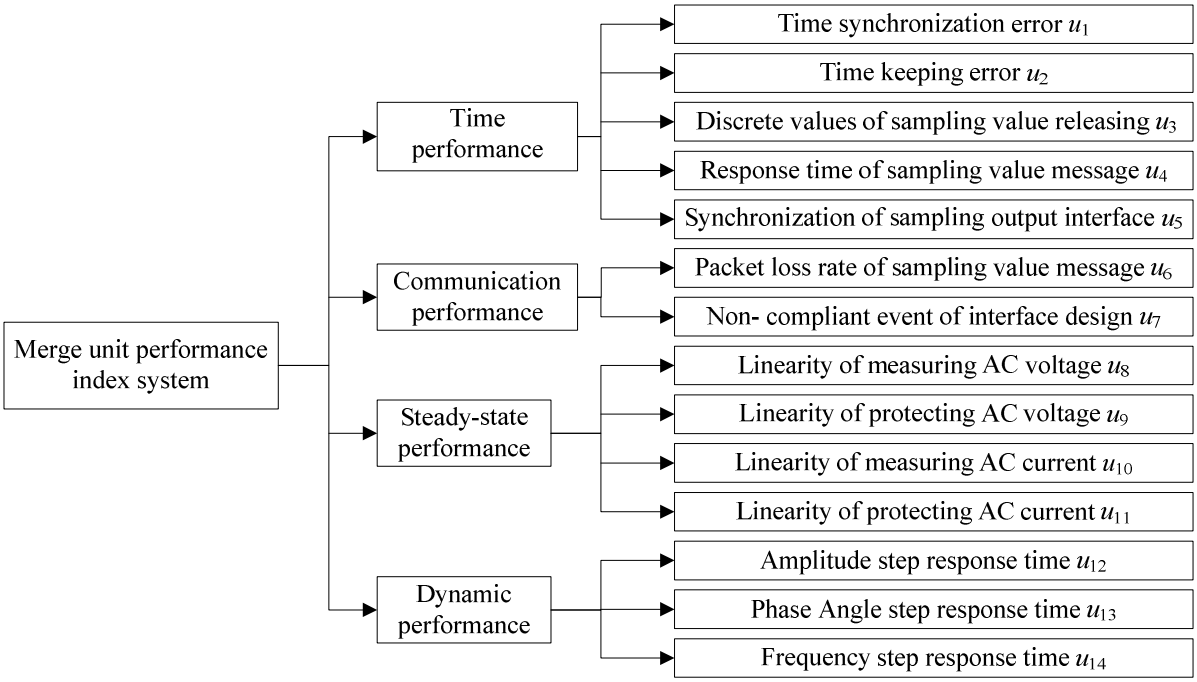

Fig.2 Performance indicators system of merging unit

Determine Membership Function

One another key of using fuzzy mathematics method to establish mathematical model is to build a practical membership function. At present, fuzzy distribution applied on engineering are matrix distribution, trapezoid distribution, parabolic distribution, normal distribution, triangular distribution, etc. According to the continuity characteristics of merging unit performance and the advantage which membership function of normal distribution can gather more information, we intend to apply fuzzy normal distribution membership function of domain for 6σ in the evaluation. The expression is as follows.

$$r_1(u)=\begin{cases}1 & ,u\le\mu_1\\ e^{-\frac{(u-\mu_1)^2}{2\sigma_1^2}} & ,\mu_1<u\le\mu_2\quad ,\sigma_1=\dfrac{\mu_2-\mu_1}{3}\end{cases}$$

$$r_2(u)=\begin{cases}e^{-\frac{(\mu_2-u)^2}{2\sigma_{21}^2}} & ,\mu_1<u\le\mu_2\quad ,\sigma_{21}=\dfrac{\mu_2-\mu_1}{3}\\ e^{-\frac{(u-\mu_2)^2}{2\sigma_{22}^2}} & ,\mu_2<u\le\mu_3\quad ,\sigma_{22}=\dfrac{\mu_3-\mu_2}{3}\end{cases} \tag{6}$$

$$r_3(u)=\begin{cases}e^{-\frac{(\mu_3-u)^2}{2\sigma_3^2}} & ,\mu_1\le u<\mu_3\quad ,\sigma_3=\dfrac{\mu_3-\mu_2}{3}\\ 1 & ,u>\mu_3\end{cases}$$

where, μ_1 is the given expectation value of "optimal", μ_2 is the given expectation value of "good" and μ_3 is the given expectation value of "general".

According to the standard for the merging unit and the practical engineering experience of relevant operation personnel, each parameter value of the membership function can be determined, as shown in Table 2.

Table 2. Parameters of the membership function

	u_1 (μs)	u_2 (μs)	u_3 (μs)	u_4 (ms)	u_5 (μs)	u_6 (%)	u_7 (%)	u_8 (%)	u_9 (%)	u_{10} (%)	u_{11} (%)	u_{12} (ms)	u_{13} (ms)	u_{14} (ms)
μ_1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
μ_2	0.5	2	5	0.5	0.5	0.05	5	0.1	3	0.1	0.5	20	20	20
μ_3	1	4	10	1	1	0.1	10	0.2	6	0.2	1	34	34	34

Example Application

Taking a type of merging unit as an example, this paper evaluates its performance with the use of fuzzy comprehensive evaluation method based on the triangular fuzzy number in Figure 1. According to the test statistics, the value of each evaluation index is U = [0.6, 1.5, 7, 0.6, 0.3, 0.04, 2, 0.17, 1, 0.13, 0.2, 10, 23, 26].

According to the hierarchical theory, the importance of each index in the evaluation index system are compared based on three experts' judgment, and the fuzzy judgement matrix is generated after taking an average. Taking the time performance as an example, the weight of each time performance index is calculated, as shown in Table 3.

Table 3. Fuzzy judgement matrix

	u_1	u_2	u_3	u_4	u_5
u_1	(1, 1, 1)	(1, 1.5, 2)	(1.25, 1.5, 2)	(1, 1.5, 2)	(1, 1, 1)
u_2	(1/2, 2/3, 1)	(1, 1, 1)	(1.25, 1.5, 2)	(1/2, 2/3, 1)	(1/2, 2/3, 1)
u_3	(1/2, 2/3, 4/5)	(1/2, 2/3, 4/5)	(1, 1, 1)	(1/2, 2/3, 1)	(1/2, 2/3, 1)
u_4	(1/2, 2/3, 1)	(1, 1.5, 2)	(1, 1.5, 2)	(1, 1, 1)	(1, 1, 1)
u_5	(1, 1, 1)	(1, 1.5, 2)	(1, 1.5, 2)	(1, 1, 1)	(1, 1, 1)

Calculate the comprehensive importance degree of every evaluation index according to the Formula (3), and the results are as follows: S1 = (0.1610, 0.2468, 0.3721), S2 = (0.1150, 0.1709, 0.2791), S3 = (0.0920, 0.1392, 0.2140), S4 = (0.1380, 0.2152, 0.3256), S5=(0.1534, 0.2278, 0.3256).

And then calculate the possibility of being more important than according to the Formula (4):

$V(S_2 \geq S_1)=0.6085$, $V(S_2 \geq S_4)=0.7610$, $V(S_2 \geq S_5)=0.6881$, $V(S_3 \geq S_1)=0.3296$, $V(S_3 \geq S_2)=0.7576$, $V(S_3 \geq S_4)=0.4999$, $V(S_3 \geq S_5)=0.4061$, $V(S_4 \geq S_1)=0.8387$, $V(S_4 \geq S_5)=0.9315$, $V(S_5 \geq S_1)=0.8965$, $V(S_1 \geq S_2)=V(S_1 \geq S_3)=V(S_1 \geq S_4)=V(S_1 \geq S_5)=V(S_2 \geq S_3)=V(S_4 \geq S_2)=V(S_4 \geq S_3)=V(S_5 \geq S_2)=V(S_5 \geq S_3)=V(S_5 \geq S_4)=1$

Plug the above results into Formula (5), and then calculate the weight: $d_1 = 1$, $d_2 = 0.6085$, $d_3 = 0.3296$, $d_4 = 0.8387$, $d_5 = 0.8965$. Get the weight after unitary: W = (0.2722, 0.1656, 0.0897, 0.2283, 0.2441).

Calculate the membership value of every index, then get the fuzzy relationship matrix R:

$$R=\begin{bmatrix} 0.0015 & 0.8353 & 0.0561 \\ 0.0796 & 0.7548 & 0.0009 \\ 0.0001 & 0.4868 & 0.1979 \\ 0.0015 & 0.8353 & 0.0561 \\ 0.1979 & 0.4868 & 0.0001 \end{bmatrix}$$

Get the comprehensive evaluation of the time performance after weighting:

$$B_1 = (0.0623, 0.7056, 0.0460)$$

Similarly, the weight of the communication performance can be obtained: W = (0.6842, 0.3158), and the comprehensive evaluation is B_2 = (0.1921, 0.6340, 0.0011).

The weight of the steady-state performance can be obtained: W = (0.3142, 0.2914, 0.2464, 0.1480), and the comprehensive evaluation is B_3 = (0.2489, 0.2677, 0.2367).

The weight of the dynamic performance can be obtained: W = (0.5375, 0.2647, 0.1978), and the comprehensive evaluation is B_4 = (0.1753, 0.4763, 0.0620).

Due to the time performance, communication performance, steady-state performance and dynamic performance being the same importance, their weight is: W = (0.25, 0.25, 0.25, 0.25), then get final comprehensive evaluation of merging unit: B = (0.1696, 0.5209, 0.0864).

According to the maximum membership principle and fuzzy comprehensive evaluation results, we can know that the comprehensive performance of the merging unit is good. In the secondary performance index, the membership degree of the time performance, communication performance and dynamic performance is bigger. In the first-level index, the situation of minority performance indexes such as Non- compliant event of interface design is excellent, the situation of linearity of

measuring AC current being general, and most of the rest of the performance index is in good condition. If the evaluation score is needed, we can set a corresponding score for each grade, and calculate the score of the merging unit performance evaluation. By evaluating score, performance can be compared between different types of merging unit, and then find out the better product in equipment selection work.

The index weight of merging unit performance calculated by the triangle fuzzy number is in accordance with the fuzziness of people's subjective thinking about relative important degree. It retains the advantage of the subjective understanding and experience to judge, and guarantees the weight objective and reliable on the algorithm.

Summary

The index weight of merging unit performance is obtained by mathematical processing with triangular fuzzy number, and can improve the defects of traditional subjective weight in a certain extent. On the above basis, a merging unit performance evaluation index system and a fuzzy comprehensive evaluation model are established, providing a systematic model and basis for the merging unit performance evaluation. The instance shows the effectiveness of using the triangle fuzzy number to calculate the index weight, and the reliability of the fuzzy comprehensive evaluation model established.

Keywords: urban road network; overpass area; ponding depth detection; travel time prediction; traffic guidance

Abstract. Overpass is an important hub for urban road network facility, its traffic capacity severely restricts that of the entire road network. Since overpass area is easy to gather water in urban road network, rain water under the overpass is an important incentive for traffic jams. In this paper, a reliable and easily maintainable method is discussed to detect the depth of the road surface water, which designs and implements a monitoring system of urban road network ponding depth. Based on this, technique of predicting travel time has been researched about overpass area under water-logging condition. Through a real example, the technique discussed in this paper has been proved to be highly effective and veracious, and can be used to provide basic data for traffic guidance to plan out sound routes.

Introduction

With the development of social economy and urbanization, the number of the population and that of the vehicles in the city is increasing. Therefore, the problem of the traffic jam becomes more serious, and meanwhile, the economic and environmental cost further restrains the development of the city. How to relieve the traffic congestion has become an important problem for all big and medium-sized cities in the world to face and to solve. To solve the problem, limiting the traffic participants, increasing the traffic network capacity and raising the traffic efficiency could be considered. However, the service function of the city requires that the city can't endlessly limit the number of the traffic participants or the time of using the traffic facilities, or the space in the city requires that the city can't endlessly increase the traffic network capacity. Moreover, it has been proved that merely depending on the increasing of the traffic network capacity can not solve but aggravate the problem of the traffic jam [1]. Under the present traffic condition, improving the operating efficiency of the traffic network is a practical way to solve the problem of the traffic jam [2]. Traffic guidance, according to the cost of a traveler driving from the starting point to the destination, provides an optimal route for the traveler to link the starting point and the destination. The traffic guidance system has been proved to be a significant method to improving the operating efficiency of the traffic network in the city. Travelling route planning is a core element of the traffic guidance, which could be attributed to a problem of looking for the shortest route of weighted directed graph. The weight of the directed graph is the link travel cost, directly influencing the accuracy of the travelling route planning.

The link travel time is conditioned by many factors due to the complexity of urban road network. Therefore, this problem has received serious attention from many researchers. The communication system between road infrastructure and vehicles, collecting the data of the roads and time of vehicle traffic at regular intervals, is used to infer vehicles' travel speed in large numbers of roads [3]. Under the premise of a license plate as vehicle identification, the travel time of urban main road is predicted by analyzing the time vehicles appeared in urban main road in the multiple surveillance

videos [4]. The detection method of road traffic flow data which is based on the signal matching method of upstream and downstream vehicle detector is studied and the prediction method on the link travel time is designed based on it. The method has good robustness for situations of traffic congestion and signal leak [5]. The prediction method on cycle and time of traffic light signal based on the road travel time is studied to predict queue length and the travel time of traffic intersection [6]. The travel time estimation model, based on the methods of step function, linear interpolation and so on, is studied in accordance with the principles of that accumulative flow can be segmented linearization [7]. The data analysis method of upstream and downstream vehicle running speed and direction is studied based on space-time queue model, then the travel time prediction method on rapid fluctuations is described based on the extracted parameters [8]. Affected by the traffic control signal, the traffic data of the downstream coil can not be used to predict travel time, so the modified method on data detected by downstream coils and the prediction method of the link travel time are proposed by studying the dynamics of the vehicle near the stop line [9]. The present studies are mainly focused on the characteristic extraction methods on the state of traffic flow states and the prediction methods of the link travel time in conventional weather conditions. However, there has been a lack of effective means of prediction in the conditions of disasters.

In recent years with the constant advancement of China's urbanization, the scale and complexity of the city road network has been also increasing. Meanwhile, as an important way to build complex road network, overpass achieves a rapid growth in number [10]. The overpass is a multilayer complex structure, so constraints of the existing city planning, traffic facilities, the surrounding buildings and other factors lead to ponding in overpass area [11]. As the hub of urban road network, the ponding in the overpass area which there have intensive vehicles and large traffic flow, will seriously affect the road network traffic capacity to cause traffic congestion [12]. Therefore, how to monitor the depth of water covering the city overpass area and how to predict the travel time are of important practical significance to ease traffic congestion and improve operation efficiency of road network under rainfall condition [13]. In this paper, the detection system based on depth of the water in overpass areas covering the entire road network is put forward and the travel time prediction model based on the characteristics of ponding existing in the overpass area is built.

Design of the Urban Water-logging Monitoring System

Overpass water points have the characteristics of a local focus and global dispersion characteristics. For example, multiple water points in overpass area are distributed in the scope of one square kilometer, but different overpasses have greater distance. Zigbee communication technology has the characteristics of low cost, high reliability and multiple ad-hoc networks. The communication technologies with mobile communications network makes wider access coverage and channel bandwidth. Therefore, the combination of the two networks to obtain the hybrid communication network has characteristics of wide coverage, high communication efficiency and low operating costs. Urban water-logging monitoring system has data interfaces with departments of traffic guidance, fire fighting and fight floods and has the ability to send short messages directionally and provide directional web services. The design of urban water-logging network monitoring system structure is shown in Figure 1.

Currently, ultrasonic ranging is the basic method of measuring surface gathered water. But the water waves caused by moving person or vehicle will significantly impact water depth measurement accuracy, and the personnel and vehicles moving under the ultrasonic sensor also decrease measurement accuracy, resulting in malfunction. To overcome these disturbances, we can use the external protective pipe to limit the movement of objects into the detection region of the ultrasonic sensor. However, because surface water contains more sediment to plug the pipe easily, there will be high maintenance costs. Based on an optical liquid level sensor, an easy maintainable urban ponding detection method is designed in this paper. The optical liquid level sensor can react to whether being submerged. Therefore the detector exposed to water avoids the problem of difficult maintenance in ultrasonic detection methods. The structure of the water depth measurement device is shown in Figure 2 based on optical liquid level sensors. The data acquisition

and transmission board based on the single-chip microcomputer to realize to measure water depth and transfer data among nodes in shown in Figure 3.

Travel Time Prediction in the Overpass Area under Water-logging Conditions

Prediction Model Design

Many factors affect travel time in overpasses area, which includes transport factors such as traffic flow, traffic state, vehicle types and road system factors such as green ratio and section length and environmental factors such as weather conditions and the surrounding public buildings. Among many factors, traffic state, traffic flow and weather conditions on the overpass area have a relatively large impact on travel time. Urban transport system is a large complex of randomness and uncertainty system. With the increase of complexity of the system, the accurate prediction of the link travel time is meaningless, and the results of a qualitative description of the link travel time accords to actual situations. Fuzzy approach is an effective method to describe uncertain problems, and therefore to process traffic-related parameters fuzzily accords to urban traffic characteristics. Assuming the link travel time is T, traffic flow F, traffic state S, water depth H, using the Self-Organized Map (SOM) method to calculate the cluster centers of the characteristics.

To assume the cluster centers corresponding to traffic flow of small, medium and large as C_{f1}, C_{f2} and C_{f3}, to traffic state of smooth, amble and congestion as C_{s1}, C_{s2} and C_{s3}, to water depth of small, medium and large as C_{h1}, C_{h2} and C_{h3}, and to traffic time of short, medium and long as C_{t1}, C_{t2} *and* C_{t3},. To assume the membership corresponding to traffic flow of small, medium and large as μ_{h1}, μ_{h2} and μ_{h3}, to traffic state of smooth, amble and congestion as μ_{s1}, μ_{s2} and μ_{s3}, to water depth of small,

medium and large as μ_{h1}, μ_{h2} and μ_{h3},, and to traffic time of short, medium and long as μ_{t1}, μ_{t2} and μ_{t3}. So L_{h1}, L_{h2} and L_{h3} is the Euclidean distance between water depth and the cluster center of that, and set the current water depth as h, then the calculation rules are:

1) If $h < C_{h1}$, then $\mu_{h1} = 1$, $\mu_{h2} = 0$, $\mu_{h3} = 0$.

2) If $h > C_{h3}$, then $\mu_{h1} = 0$, $\mu_{h2} = 0$, $\mu_{h3} = 1$.

3) If $C_{h1} < h < C_{h3}$, then memberships to three categories is $\mu_{h1} = L_{h2} / (L_{h1}+L_{h2})$, $\mu_{h2} = 1- \mu_{h1}$, $\mu_{h3} = 0$, when $L_{h1} < L_{h2} < L_{h3}$.

For other situations, the degree of membership is calculated as above. Similarly, the degrees of memberships of traffic state, traffic flow, and travel time can be obtained according to the above method. In this paper, the degree of memberships, as input parameters, are used to predict the link travel time by BP network.

Verification of an Example

Extraction of 50 samples tested under Jinyuan bridge in Shijingshan District of Beijing from May 20, 2013 to August 20, 2013 is used to verify the proposed method after normalization. The location of the sample data collected and verified is shown in Figure 4.

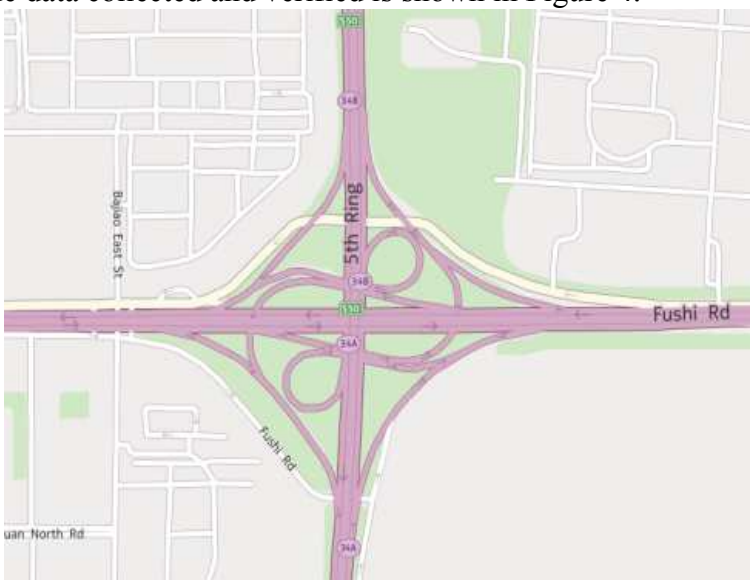

Fig.4. The location map of sample data collected

The clustering centre data computed by SOM is shown in Table 1.

Tab.1. The clustering centre data

C_{f1}	C_{f2}	C_{f3}	C_{s1}	C_{s2}	C_{s3}	C_{h1}	C_{h2}	C_{h3}	C_{t1}	C_{t2}	C_{t3}
0.389	0.672	0.831	0.152	0.328	0.456	0.217	0.587	0.652	0.028	0.439	0.842

Put the membership data of test samples into estimating model of the travel cost of traffic overpass area which is trained by Back Propagation under the condition of rainstorm, and calculate out the estimation results of the degree of membership. The data of actual results and estimation results are shown in Table 4. The deviation is the distance value between actual value and estimated value. The calculation method on deviation value is:

$$\varepsilon = \sqrt{\sum_{i=1}^{3} (C_i - \hat{C}_i)^2} \tag{1}$$

In the type: C_i stands for the actual value of the degree of membership of the travel cost; $\hat{C}_i$ stands for the estimated value of the degree of membership of the travel cost.

Tab.4. The comparison between estimated simulation results and actual results of traffic capacity in overpass area under water-logging condition

Conclusion

In this paper, a detection method on the depth of the road surface water is discussed under the condition of urban water-logging, which designs and implements a monitoring system of urban road network ponding depth. In the meantime, a prediction model of the link travel time has been set up

by Back Propagation, which is based on traffic flow, traffic state and the depth of the road surface water. Through a real example, the technique discussed in this paper has been proved to be highly feasible and effective to predict the link travel cost under the condition of urban rainstorm.

Keywords: Information Technology; Engineering Thermodynamics; Blending Teaching

Abstract. Information technology has been greatly developed in recent years and brings opportunities as well as challenges for engineering courses. This paper surveys the development and characteristics of information technology. Then different methods of information technology are analyzed and applied. The new teaching mode based on information technology – blending teaching as well as detailed teaching case is proposed in the course of Engineering Thermodynamics.

Introduction

The booming development of information technology has greatly influenced higher education. Information technology brings opportunity as well as great impact on education industry especially higher education industry. Governments from different countries pay great attention on information technology in the last decade. In 2010, U.S. Department of Education announced national education technology plan [1]. Technology, especially information technology is proposed to transform and motivate the American future education in this plan. Chinese government also thinks highly of information technology and has proposed a series of steps to improve education development by information technology. In 2012, Ministry of Education announced "Ten-year development plan for education informatization from 2011 to 2020". In this plan, how to discover the comprehensive and deep integration of modern information technology with education to guide the innovation of modern education concept and education mode is proposed [2]. How to effectively make use of information technology in higher education field, especially for engineering courses are intensively focused in universities in recent years.

This paper first surveys the development and characteristics of information technology. Then, combined with course of Engineering Thermodynamics, different methods of information technology are analyzed and applied for this course. In the last part of this paper, the new teaching mode based on information technology – blending teaching in Engineering Thermodynamics as well as detailed teaching case is proposed. The main purpose of teaching and research in information technology is to carry out teaching reform and promote teaching effect of Engineering Thermodynamics in universities.

Characteristics of Information Technology for Higher Education

Traditional classes in universities have been applied for centuries. However, traditional classes also have the disadvantages of one-way teaching, passive accepting, and "duck-stuffing" teaching mode, etc. How to change traditional education, activate the creativity of students, improve the quality and ability of students, and pursue the development of individualized students, is the new teaching research topics we faced.

The development of teaching mode in universities has experienced four main steps: the first step is traditional classes, this mode is teacher-centered teaching mode which means teachers are the center of classes while students are in the passive role; the second step is apply information technology to support teaching processes which means teachers use some digitized resources such as electronic teaching plan, PowerPoint presentation, network teaching platform to assist the

teaching processes; the third step is the application of network-assisted teaching, which means network teaching accounts for a large proportion of the classes contrast to face to face teaching; the fourth step is online courses which means most classes or entire classes are taught by website online processes. Table 1 shows the development of information technology and their relationships in recent years in both USA and China [3].

	Face-to-face class process	IT support teaching process	Network assist teaching process	Online course process
Characteristics	Traditional teaching mode, no network teaching hours	Less than 30% network teaching hours	About 30% to 70% network teaching hours	More than 70% network teaching hours
USA progress	Before 1999	1999-2004 Risk investment on business corporations such as Blackboard and WebCT	2005 to now About 3000 universities use Blackboard	2012 to now edX, Coursea, Udicity MOOCs platform are constructed and applied widely
China progress	Before 2003	2003 to now Digital resources platform, course website, qualified course construction	2007 and 2008 Some universities discover teaching reform and innovation for some courses	2013 to now First year of MOOCs in China, and some famous universities issued MOOCs

Application of Information Technology in Engineering Thermodynamics

Information technology brings opportunities as well as challenges for engineering courses. The following part of this paper studies construction and application of Information Technology in Engineering Thermodynamics.

1. Application of digital resources in Engineering Thermodynamics

Digital university campus has been universal in China in recent years. Construction of digital resources for university courses may be regarded as part of digital campus. How to popularize and improve the digital resources for engineering courses should be focused by all the teachers and educators.

Digital resources for Engineering Thermodynamics include electronic teaching resources: course introduction, course specification, teaching plan, key and difficult problems, exercises in the class, exercised after class, references, PowerPoint presentation, exercise library, example library, lecture library, material library, academic paper library, further reading library, micro teaching voice library, micro teaching video library, etc.

All the digital resources should cover the fundamental knowledge, basic concepts, basic principles, typical cases, advanced topics, and hot issues in Thermodynamics field. For examples, hot issues can involve renewable energy issue, new energy issue, high-capacity power unit issue. During the construction process of digital resources, to actualize systemic and entire course resources as basic requirement, to actualize rich resources and open resources as basic goal, to make good service for the teaching and learning process as key point, to fulfill and improve actual reaching requirements as ultimate goal.

2. Application of network resources in Engineering Thermodynamics

As the products of information technology, micro courses and MOOCs (Massive Open Online Courses) is popular all around the world in recent years. Micro courses and MOOCs have the characteristics of online, open, transparent courses, which provide easy and friendly studying mode for students. With the increase of widely distributed students in the whole world of micro courses and MOOCs, new requirements including course content, knowledge structure, knowledge

classification, studying arrangement are proposed for the network courses. For engineering courses, the key step of course design is to tease out knowledge points and rebuild the knowledge structure in the proper form of MOOCs. According to the characteristics of Engineering Thermodynamics, how to classify the course content and knowledge structure reasonably to ensure each course unit is one complete knowledge point and close relations and fusions among these units, is the most important step to build network course. Besides course design module, other modules such as discussion unit, class instruction unit, interaction unit, Q&A unit, exercise unit, examination unit are also need to be designed reasonably and interspersed rationally in the whole network course [4]. At the same time, diversity and personality should be considered to attract the students' learning interest.

3. Blending teaching exploration in Engineering Thermodynamics

One new teaching mode based on information technology – blending teaching is carried out in the course of Engineering Thermodynamics. Blending teaching is different from traditional teaching mode, which employs a large proportion network teaching as well as face-to-face classes. There are three steps to perform the course teaching: face-to-face class, video course online, discussion class. Students can learn the important course contents through self-study in the course website online by video course. While in the classes, teachers solve problems which students can not deal with online and discuss with students for further study of the course. Discussion is also carried out online by teachers and students or even students and students. This kind of teaching mode can utilize fully of the advantages of modern information technology and make up the disadvantages of traditional teaching. To mobilize the interest of students, teacher organizes students to discuss interested issues or difficult issues in classes, no need to teach course contents in the classroom, and which can be called as flipped classroom. That means teacher can focus on the guided education to improve the thinking ability and creativity ability of students. Meantime, students' interest is improved since students can utilize their spare time and their best status to study the online course. Blending teaching and flipped classroom transform the teacher-centered teaching mode to student-centered teaching mode. Teaching case for moist air in Engineering is designed according to the concept of blending teaching and flipped classroom. Figure 1 shows the teaching case based on blending teaching in Engineering Thermodynamics [5].

Conclusion

In this paper, different information technology, such as digital resources, micro course, MOOCs, blending teaching, flipped classroom is analyzed and applied. Detailed teaching case for the knowledge of moist air is also proposed and applied in the course of Engineering Thermodynamics.

Keywords: Shanghai; Wastewater; Environment; City; Management

Abstract. In 1981~2012, the general urban wastewater in Shanghai was between 1.775~2.420 billion tons. Among the urban wastewater, the industrial wastewater emissions before 1988 was more than 1.4 billion tons, then, it was declining to about 649 million tons at 2002, a low value in the past 30 years, less than 50% of the 1980s. The percentage of industrial wastewater in the total urban wastewater discharge is falling from 76.9% in 1981 to under 30% in recent years. The living wastewater emissions increased from 424 million tons in 1981 to 1.697 billion tons in 2012. There is a relationship between the living wastewater increasing and the increase of the permanent residents in Shanghai. At the same time, the living wastewater emissions per capita per day were significantly increased from 100 kg (liter) around 1980s to around 190 kg (liter) in recent years. From 1995, the treatment and management of urban wastewater was continuing to intensify in Shanghai. The ratio of wastewater treating has increasing from 6.35% in 1995 to 85.62% of the total urban wastewater in 2012. Comparing the social-economic development and management of wastewater discharge in Shanghai, it can be seen, the wastewater emissions increasing amplitude was far less than the sizes of population growth and economic growth in the past 30 years

Introduction

Shanghai is located at the west bank of Pacific Ocean, the east frontier of the Asian continent, the center of the China coast. She faces to the East China Sea, bounds by Hangzhou Bay at the south, and neighbors with the Yangtze River at the north, is situated in the Yangtze River estuary. The area of Shanghai is 6340.5 square kilometers, the geographic coordinates is between latitude 30º40'N to 31º53'N, longitude 120º52'E to 122º12'E. She is part of the alluvial plain of the Yangtze River Delta, belongs to a subtropical monsoon climate.

Shanghai is China's largest municipality, a prosperous international metropolis, and an economic and financial center. Shanghai's GDP in 2012 was 2.018 trillion Chinese Yuan. The imports in Shanghai accounted for 17.1% and exports accounted for 24% of the whole nation. The population of permanent residents in Shanghai is more than 25 million; the resident's foreign population is more than 170 thousand people.

Water environment is related to the city's survival and the sustainable development of society and economy. Water environment management is one of the main missions of the Shanghai municipal government, the management of urban wastewater is the key work. There are the Shanghai Water Bureau and the Environmental Protection Bureau to take charge the work. In recent years, with the improvement of living standards of Shanghai and the rapid increasing in population, the pressure on water resources and environment is increasing rapidly. The water pollution incident has been reported from time to tome, the status of water environment is being more and more social attention.

Here by collecting data, analyzing the wastewater discharge and treatment, and comparing with relevant data of economic and social development of Shanghai since 1981, to discuss quantitatively the annual variability of urban wastewater management and the relationship with economic and social development; to reveal the trend of wastewater management at environment protection; to make society understanding the relationship between wastewater management and the public, for further improving urban wastewater management system.

Data Source

To ensure the reliability of the analysis, the data are only chosen from the Water Environmental Quality Communiques, Water Resource Bulletins, Newsletters, Year Books, which were published by government administrations at different years, such as the Shanghai Environmental Protection Bureau, Water Bureau, Shanghai Statistical Yearbook, etc. and the research reports and data collections from the staff in the institutes and departments of government management; to extract the relevant data. The data used to see references[1-7].

When meeting the deviation in the data for the same year, the original of the data from the management departments and the report from collecting staff would be considered firstly, and refer to the tendency of the data before and after a few years.

Analysis and Results

The change of the wastewater emissions in Shanghai from 1981 to 2012

1). From 1981 to 2012, the total amount of wastewater discharge in Shanghai was between 1.775- 2.420 billion tons. During the years, the wastewater emissions became minimum at 1982 and maximum at 1996. The emissions decreased after 1996 and increased again since 2003 (Figure 1).

2). The discharge of industrial wastewater (IW) was higher before 1988, more than 1.4 billion tons; the discharge was declining to about 649 million tons at 2002, a low value over the past 30 years, less than 50% in the 1980s. For last decade, the industrial wastewater emission has been maintained between 647 to 759 million tons per year (figure 1).

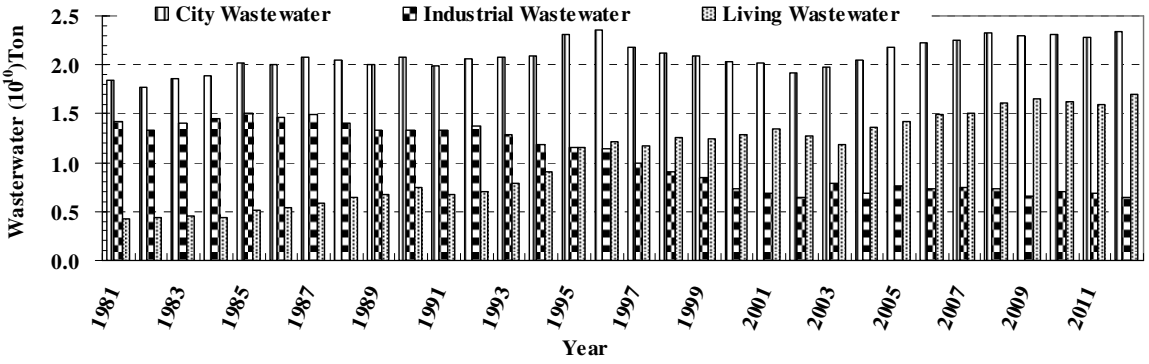

Fig. 1 The Shanghai city wastewater discharge during 1981-2012

The ratio of the industrial wastewater discharge in total city wastewater has continued to decline, from 76.9% in 1981 to less than 30% in recent years.

The Chemical Oxygen Demand (COD) emission by the industrial wastewater has been descended from 250 thousand tons at the year of 1990, to 26.2 thousand tons at 2012, about ten percent of the COD emission in 1990 (figure 2). The drop rate can be divided into two stages, before the year of 2000, the falling rate was up to 17 thousand tons per year; slowed decline rate, at about 2.45 thousand tons per year after 2000.

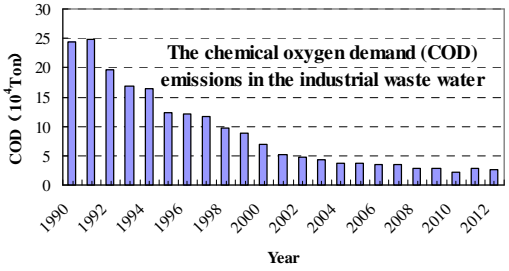

Figure 2 Annual variability of the chemical oxygen demand (cod) emission in the industrial waste water

The amount of industrial wastewater emission for the second industry output value per ten thousand Chinese Yuan, has fallen from 577.51 tons in 1981, to 8.24 tons in 2012 (figure 3). The

annual declining rate of wastewater discharge, reached 33.6 tons for the second industrial output value per ten thousand Chinese Yuan from 1983 to 1999, the annual declining rate of wastewater discharge, reached 2 tons in 2000-2012.

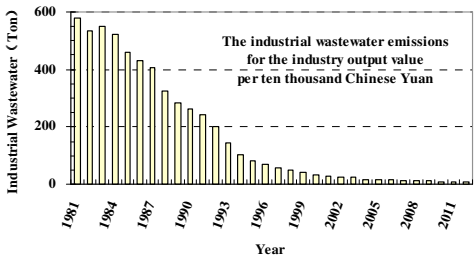

Figure 3 The annual variability of industrial wastewater emission for the second industry output value per ten thousand Chinese Yuan

3). The life wastewater discharge in Shanghai, showed a fluctuant increasing trend since 1981 generally, with some short-term negative growth in 1990-1991, 1996-1997, 2001-2003 and 2009-2010 (Figure 1).

There is a relationship between the life wastewater emission and the population of permanent residents in Shanghai. Comparing the data, it showed, with the increasing of the population, the wastewater emission was increasing. But it was not a simple linear relationship between the two (Figure 4a left), when the population was around 15 million, the increasing rate of wastewater was in turn; more than 15 million people, the growth rate of life wastewater emission was decreasing.

At the same time, the life wastewater emission per person per day were also greatly increased since 1981. It was around 100 liters emission per capita per day at the early 1980s, increased to 150 liters at 1990, up to a peak of 228.74 liters on 1996. During 1996-2001, the value was around 220 liters. In recent years, the average wastewater discharge per capita per day was falling under 200 liters (Fig 4 b, right).

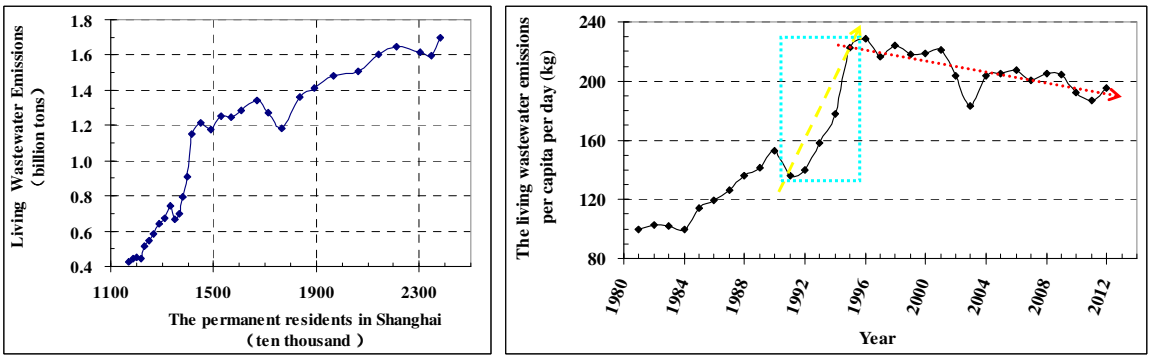

Figure 4a (left). The relationship between the life wastewater emission and the population of permanent residents in Shanghai

4b (right). The annual variability of the life wastewater emission per person per day in Shanghai

The wastewater management in Shanghai

Since 1995, Shanghai was continuing to increase the intensity of urban wastewater treatment. In 1995, the city has 17 sewage treatment plants, the wastewater treatment was 146.65 million tons, accounting for 6.35% of the total urban wastewater; to 2012, the sewage treatment plants has increased to 53, the treating capacity can be 2.01 billion tons, accounting for 85.62% of the total urban wastewater. From 1995 to 2012, with averaging, 2.1 new wastewater treatment plants were annually built, the treating capacity increased 135.73 million tons each year, and the increasing rate for wastewater treatment has 5.86% per year.

The process of wastewater management presented in the three phases by the inter-annual variability of wastewater treatment capacity and treatment rate. The first phase from 1995 to 2003, an average annual increase of wastewater treatment capacity was 31.84 million tons, an average annual increase of treatment rate was 1.77%. The second stage was between 2003-2006, the average annual increase in the amount of wastewater treatment was 370.04 million tons, an average annual increase of treatment rate was 15.81%, increasing about 10 times compared with the first stage. The years of 2006-2012 are the third stage, the wastewater treatment capacity increased by 81.56 million tons annually, the average annual treatment rate increased 3%.

The economic and social development and wastewater management in Shanghai

Shanghai's gross domestic product (GDP) increased with year since 1978. The growth rate can be divided into the three stages, turning points were at 1990 and 2002 respectively. From 1978-1990，annual growth rate was 0.4567 ten billion Chinese Yuan. The growth rate reached 4.587 ten billion Chinese Yuan per year from 1991 to 2002, about ten times is that of the previous stage. The growth rate was further increased in 2002-2012, reached to an annual 14.962 ten billion Chinese Yuan, 3.26 times compared with the stage between 1991 and 2002. The economy began rapid growth since 1991, and has continued to accelerate from 2002.

The population of permanent residents in Shanghai has continued to increase since 1978. The increasing amplitude could be divided into two stages, the turning point was in 1997. From 1978-1997, the population increased from 11 million to 15 million, the increasing rate was 192.77 thousand person annually. To 2012, the resident population increased to 23.8 million; the increasing amplitude was 653.66 thousand persons per year during 1997-2012, it is 3.39 times of the previous stage.

The GDP per capita in Shanghai was around 1500 us$ during 1978-1994. From 1994, it continued to grow. The growth could be divided into two phases, with a turning point at 2002. Between 1994 and 2002, the annual GDP per capita increased from 1,662 to 4,103 us$, with an increasing rate of 304 us$ per year. Since 2002, the growth of GDP per capita has accelerated, the annual increase was 1,021 us$, is 3.36 times of the previous stage; the GDP per capita reached 13,524 us$ at 2012.

For the annual variability of the total wastewater emission in Shanghai, three stages can be divided, the turning points are at 1996 and 2002. In 1981-1996, the wastewater emissions were annually increasing, the increasing rate was 28.4 million tons per year. The total wastewater emissions showed a downward trend during 1996 to 2002, the decrease was 59.9 million tons per year. From 2002, the total wastewater discharge again showed an increasing trend, the increasing rate was 40.6 million tons per year.

Contrast the social and economic development and wastewater management in Shanghai, it can be seen, since 1981, the Shanghai population has increased 2.04 times, the total economic output grew 62.14 times; but the total urban wastewater discharges increased only 1.28 times; the increasing amount of the wastewater discharge is far less than the magnitudes of the growth of population and economic. Since the year of 2000, Shanghai resident population has increased by 650,000 annually, per capita GDP has increased by nearly 1,000 us$ per year, the amount of the industrial wastewater discharge has maintained a low level in past 30 years, the life wastewater emission per capita has appeared a downward trend.

Conclusion

1) From 1981 to 2012, the total amount of wastewater discharged in Shanghai is between 1.775 - 2.420 billion tons.

2) The industrial wastewater emission in Shanghai before 1988 was higher, at more than 1.4 billion tons; to 2002, decreased to about 649 million tons, a low value in the past 30 years. The ratio of the industrial wastewater in the total city wastewater continued declining from 76.9% in 1981 to less than 30% in recent years. The amount of industrial wastewater emission for the second industry output value per ten thousand Chinese Yuan, has fallen from 577.51 tons in 1981, to 8.24 tons in 2012.

3) The life wastewater emissions have an increasing trend with volatility, from 424 million tons in 1981, up to 1.697 billion tons in 2012. Compared with 1981, the life wastewater emission per capita was also a substantial increase, from 100 kg for per capita daily at the early 1980s, to around 220 kg in the year of 2000, but dropped to about 190 kg in recent years.

4) Since 1995, Shanghai has continued to intensity urban wastewater treatment. From 1995-2012, an average 2.1 new wastewater treatment plants have been built annually in Shanghai, with an annual increasing capacity of 135.73 million tons, and annual increasing rate of 5.86% on wastewater treatment. By 2012, sewage treatment has reached 85.62% of the total urban wastewater discharge.

5) Compared the social-economic development and wastewater management in Shanghai, for past 30 years, the population has increased 2.04 times, the total economic output grew 62.14 times; but the city wastewater emissions increased only 1.28 times in Shanghai; the increasing amount of the wastewater discharge is far less than the magnitudes of the growth of population and economic.

The Implementation Of Network Teaching Resources Sharing Center Based On Google Cloud

Hui e Chen

Tianhe College of Guangdong Polytechnical Normal

University GuangZhou 510540

E-mail: yifanchenchen@163.com

Key words: Resources Sharing;Google Cloud

Abstract. The traditional network mode of resource sharing Easily lead to "information island", The link between information not unimpeded,With the development of information technology in education, The Google cloud network will break caused by geographical environment restricted resource barrier, Let the school quality curriculum and teaching resources sharing,Fully guarantee the fairness of education.

Introduction

This paper presents research program of teaching resources sharing based on google cloud network,A collection of cloud computing technology,The development technology of Web development platform,Using the advantages of cloud computing,To eliminate the "information island",Teaching can solve the uneven distribution of resources.

Google App Engine System

Google App Engine is a web application developed by google, In general, the online application service Google App Engine for developers to provide application development, application maintenance, operation and application of the host server and automatic upgrade.

As the network application service platform, App Engine architecture can be divided into three levels: The first layer is a data storage layer at the bottom of all the core technology, relying on the GFS Chunk Server and BigTable to construct the google infrastructure, Provides storage for Google cloud computing; The second layer is the web server layer. App Engine applications through CGI protocol and server communication;The third layer is the application layer. With the code repository and the module, designed for operating environment for the Python programming language.At present, App Engine using Python 2.5.2 version as the runtime environment.

Design Ideas

1） System Structure

The traditional network teaching resources sharing platform, is the university courses and resources sharing curriculum resources for unified management,Implementation of all the teachers and students of the sharing of resources, but in the process of teaching teachers and students will produce all kinds of teaching resources is the lack of flexible management document,

At the same time, also has the higher cost of repeated construction and maintenance. Cyber source sharing platform based on cloud computing, can realize the flexible management and good response is good, soft hardware also has high sharing and lower the cost of management and maintenance.

2）Function Module

Google cloud network teaching platform based on resource sharing, from the functions are divided into 6 functional modules, namely: Sharing center , My cloud space, Resource upload, Resource search and download, Resource management, System management.

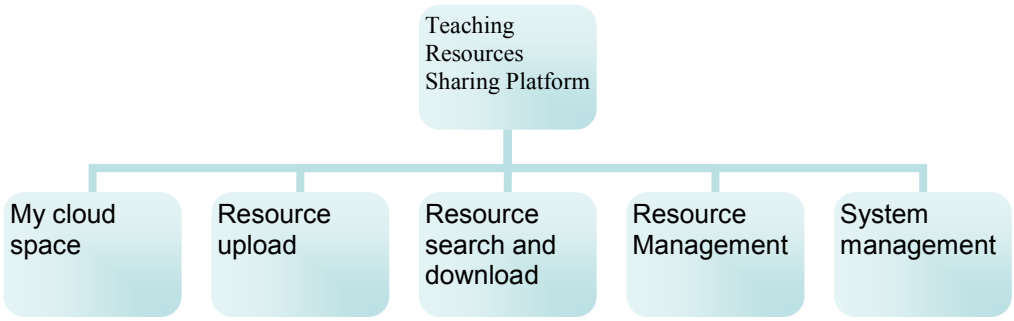

Fig.1 The structure is shown below:

Google cloud network teaching platform based on resource sharing, technology scheme using JavaEE+Google App Engine mixed development, development platform for the eclipse. The system uses the B/S structure, The Google App Engine for the development of the python language, before using the google website to register to download jar package, JSP ActionServlet page by submission, In the ActionServlet and Google App Engine, DataStore and Memcache processing all kinds of access request data, call the Google cloud services.

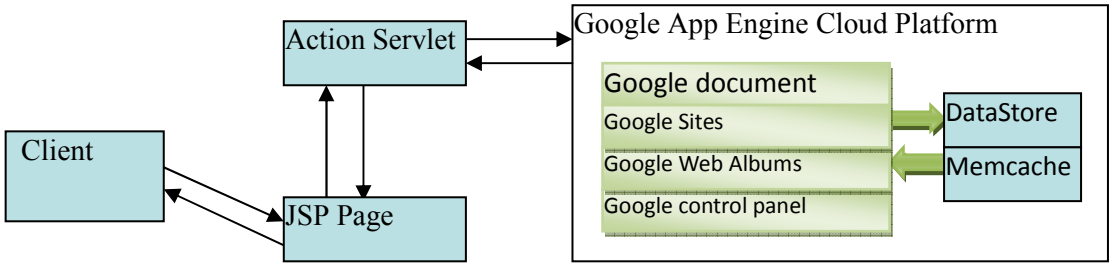

Fig.2 The structure is shown below:

In the development of JavaEE+Google App Engine hybrid,Servlet cannot use the thread, Struts start to start the manual mode, can be added to the project a set Servlet starting level of following the Web service startup,Add a Servlet listener or to the project, Struts is initialized in the listener to initialize the event, to achieve the following:

```
public class StrutsStartAdapter implements ServletContextListener {
    public void contextInitialized(ServletContextEvent servletContextEvent) {
        OgnlRuntime.setSecurityManager(null);
    } }
```

At the same time of the configuration of Struts in the Spring applicationContext.XML file modification, need to configure the stmts.objectFactory attribute value integration development process.Set the value of the struts.objectFactory property in the stmts.properties<constant name="struts.objectFactory"value="spring"/>.Then the configuration of Spring listener. Add the following content in the web.xml file <listener><listener-class> org.springframework.web.context.

ContextLoaderListener</listener-class></listener>

3）Database Table Structure

The network teaching resources sharing platform system, the database consists of 6 tables, respectively is the user information table, resource information table, resource category table, resource evaluation table, on the message list, department table.

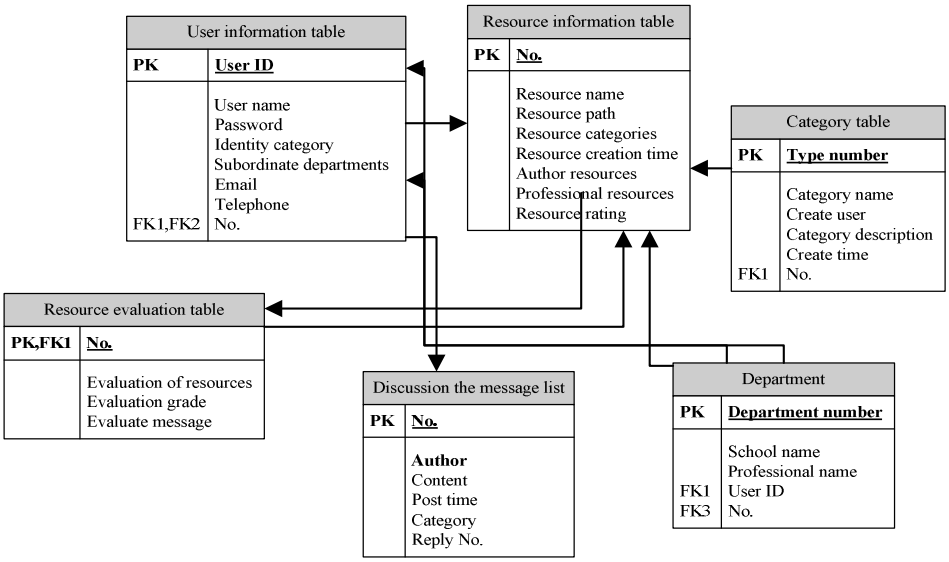

Fig.3 The structure is shown below:

4）Implementation Process

Google App Engine platform,did not provide database such persistence solutions,Instead of using a similar Bigtable technology and database persistence solutions, The Bigtable data is stored in a data storage area,And SQL is similar to GQL query language. Fig.3 table and any data logic relationship using JDO standard implemented in java,At the same time should create a JDOConfig.XML in the Web-INF configuration file when using JDO,The database table is shown to achieve the following code persistence:

```
public class User { @PrimaryKey
@Persistent(valueStrategy = GeneratorStrategy. IDENTITY)
private Key key;
@Persistent
private String usemame;
@Persistent
private String password;
@Persistent
…….
```

The data store using each Google App Engine platform in the request for a new instance of the PersistenceManager class.Examples of the use of PersistenceManagerFactory to complete the database crud operations.

For example, write to the database:

```
PersistenceManager pm = PMF.get().getPersistenceManager();
        try {                pm.makePersistent(accBean);        }
 finally {                pm.close();        }
```

Implementation Effect

The system uses Google App Engine cloud platform, The use of eclipse development tools. Give full play to the advantages of Engine platform Google App.

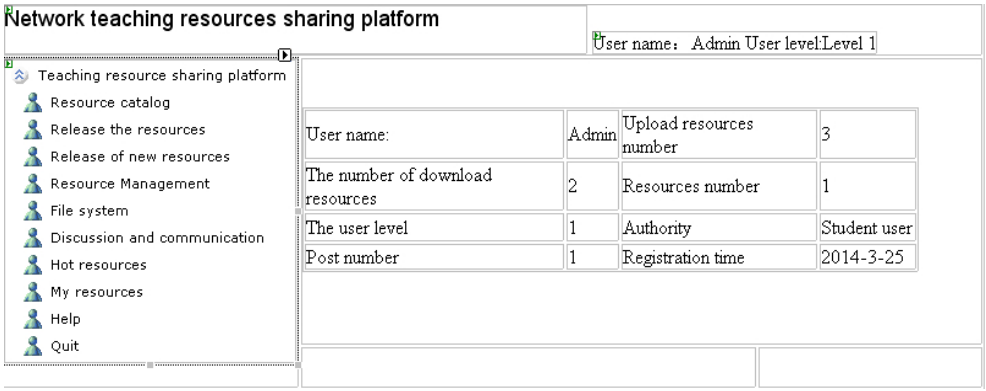

Fig.4 The effect of network teaching resources sharing platform:

Summary

This paper introduces the realization of network teaching resources sharing platform Google App Engine platform cloud technology,Google App Engine cloud platform technology compared with the traditional development technology has great advantage, summed up in the following points:

1) Good computational ability, Google App Engine using distributed technology, resources can be distributed to multiple server unified management, the service ability is not a single server can match.

2) Security is good, because Google App Engine using distributed technology, the distributed storage resources, good fault-tolerant performance, realizes the data a server will not damage the system data damage.

3) It is easy to develop and expand.

Study on the Environment tax realize ecological compensation in China

Liyuan Xu [1, a]

[1] Jiangxi University Of Finance and Economics, NanChang, 330013, China

[a]email:xly1912@163.com

Keywords: Environment Tax; Ecological Compensation; tax differentiation system

Abstract. The environment tax provide capital source for ecological compensation, Although the environment tax legal system give a guarantee for the environment and conservation of resources, The current environment tax legislation is lack of ecological compensation concept, lack of the preferential tax policy for different areas, and the funds of ecological compensation is limited. But the environment tax has irreplaceable function for realize ecological compensation, We should establish a set of environment tax law system, establish environment tax differentiation system and improving existing environment tax redistribution system.

Introduction

The ultimate goal of environmental taxes and ecological compensation is sustainable development. The environment tax provide capital source for ecological compensation.

Environmental taxes and ecological compensation through design and implement a series of systems, play a role to regulating human behavior and protect the environment, to some extent alleviate the contradictions between environmental protection and economic and social development.

The Relationship between Environment Tax and Ecological Compensation

The common theoretical basis

The economic base of environmental taxes and ecological compensation is externality theory. Due to the integrity and regional features, ecological environment have typical externalities. The behavior that somebody use natural resources result in ecological environment destruction or pollution, it inevitably influence others to use natural resources, cause external diseconomy (negative externalities); somebody pay a huge cost to protect the natural resources, he will get profits, and others are also get the benefits, the external economy (positive externalities) is produced. Environment tax system mainly solves the problem of negative externalities, the government levy tax on these external diseconomy behavior of pollution and damage to the environment, let the impairer get the damage cost, thus make the internalization of external costs; Ecological compensation mainly to promote the sustainable development of positive externalities, government design and realize secondary benefit distribution for the environmentalist and beneficiary by means of the compensation (subsidy) system, it can make the environmental beneficiary pay the reasonable cost benefit, so ,all people can enjoy the sustainable ecological benefits.

Environmental taxes and ecological compensation all reflect ecological justice value. What is the ecological justice? It is a complex problem. From Rawls's justice view, through design the reasonable system, it make all the social basic value -- the freedom and opportunity, income and wealth, self-esteem, get the equal distribution, unless one or all of the value of an unequal distribution are conform to everyone's interests.[1] So, in the field of environmental protection, it should comply with the essence of the ecological justice when seek the balance of different interests and development opportunities and coordination. A large number of external effects of environmental are huge ecological injustice, pollution, damage to the environment, but do not bear the corresponding cost, protection, construction of ecological environment has not been returned. The purpose of levy environment tax and the implementation of ecological compensation is to make the related bodies assume the responsibility, restore fair environment, realize ecological justice.

Environment tax provide stable sustainable sources of finance for ecological compensation

Ecological compensation is one of effective environmental economic means for environment protection and utilization, it has been widely used in the world, include China. The methods of ecological compensation in China is still the government investment or government transfer payment system, the government pay is doubtless true, but in the long run, the subsidies can lead to low efficiency, lead to a new "policy failure", such as economic undeveloped areas become dependent, lose endogenous support capacity, etc. Some local governments in China are exploring the market mechanism for ecological compensation measures (such as water rights trade), but the market mechanism and the area between voluntary consultation mechanism is not yet fully established, lack of funds is still the key obstacle for ecological compensation. Environmental tax can make the tax earmark a fund for its specified purpose only. Provide the continuous steady capital source for ecological compensation. Foreign environment tax law practice, the environment tax revenue as compensation for sacrifice development opportunities for ecological environment protection and construction, or used as a special fund, only dedicated to control environmental pollution and improve the environment, and so on, it is generally not allowed to move for him.

The Practice and the Existing Problems of Environment Tax Realize Ecological Compensation in China

In China, the environment tax play a role ecological compensation mainly include resource tax, consumption tax, urban maintenance and construction tax, cultivated land usage tax, urban land use tax and vehicle and vessel tax. Although the original intention of these taxes is not to environmental protection, but they have certain ecological characteristics, and have played an important role in saving resources, protecting the environment. In accordance with the law, the resource tax on crude oil, natural gas, coal, other non-metal ores, ferrous metal ores and non-ferrous metal ores and salt. Consumption tax in our country at the beginning of the set up is not considered taxable products produced by the external environmental cost, but the most of taxation scope have the characteristics of the environmental protection, such as covering the firecrackers and fireworks, motorcycles, cars, golf balls and ball, wooden disposable chopsticks, real wood floor and other 10 kinds of consumer goods. Urban maintenance and construction tax earmark a fund for its specified purpose only, guarantee for urban public utilities and public facilities maintenance and construction, in practice, it has become a important source of funding for flood control and drainage, afforestation, environmental health and other, as a "special tax" for environmental protection and ecological compensation. Cultivated land usage tax protect the cultivated land, forest land, grassland, water and fishery waters of the tidal flats, and other scarce resources. Urban land use tax promotes the rational use of urban land resources; improve the efficiency of land use. The article 4 of vehicle tax law stipulated in, "for saving energy, the vehicle that using new energy can be exempted or reduced tax", it embodies the national "friendly" attitude for energy.

The other tax about ecological compensation, for example, added- value tax, income tax, fixed assets investment adjustment tax, all directly or indirectly contains tax preference for environmental protection, they have played a certain role in ecological protection. Such as the regulation of "interim regulations on value-added tax" (2008), taxpayers selling or importing water, heating, air conditioning, hot water, coal gas, liquefied petroleum gas, natural gas, methane gas, household use coal, chemical fertilizers, pesticides, agricultural films, such as apply to the low rate of 13%; the ecological degree of income tax law is higher, have a number of environmental protection terms,and so on.

In practice, these ways play an important role to reduce environmental pollution, promote the comprehensive utilization of resources. But there are still the following problems:

First, the concept about ecological compensation in environmental tax law is deficient. There are common theoretical basis, such as the environmental externalities, sustainable development and maintaining ecological justice, in environment tax and ecological compensation, but it is difficult to find the "resonance" in the reality legislation. The purpose of related environment tax legislation in our country are mainly economic development and people's livelihood security, such as the

consumption tax, aims to regulate the consumption structure, guide consumption direction, suppress premature consumption and increase revenues. The effect of environmental protection is derived. The ecological compensation, derived from the environment tax legislation, reflect compensation indirectly for environment, it does not refer to the compensation for those people who make contributions or get sacrifice because protect environment and construct ecological environment, in addition, with the insufficient funds, it may deepen the plight of the ecological compensation. Because of the awareness on ecological compensation for the contributors and the victims is confused in practice, some people about Dongjiang River compensation consider, the water resources are owned by the state, the protection of water resources is everyone's responsibility. To some extent, Guangdong province is the owner and the beneficiary of Dongjiang river basin water resources, but at the same time, Guangdong province not only get own economic development, but also made due contributions to the nation. Therefore, our country should establish ecological compensation, the transverse compensation between local governments is not realistic.[2]

Second, it is very limited that the environment taxes realize ecological compensation. The ecological compensation fund quantity is very limited. For example, the national resources tax in 2010 are 417.55 billion yuan, only accounted for 0.54% of national total tax revenue, urban maintenance and construction tax 1887.09 billion yuan, accounting for 2.4% of the national total tax.[3] so, our country environment tax is too scattered, too small, accounted for the proportion of tax revenue is too low. It is difficult to play the role of regulation and guidance of environmental protection effectively. The more important thing is the lack of regional preferential tax. Our country set up regional preferential tax system in view of the special economic zones, coastal economic development zone, economic and technological development zone, hi-tech industry development zone, in the west areas and poor areas. But from the perspective of the content of system, they are based on preferential productive enterprises with foreign investment as the main object, the main favorable means for enterprise is that the income tax shall be levied at the reduced tax rate of 15% or 24% discount directly,without considering the resources endowment of the upper Midwest, natural conditions, location advantages and differences in the different region, it is difficult to promote the region economy coordinated development.

The Legal Thinking about Environment Tax to Realize Ecological Compensation in China

Propos establish “environment compensation tax” instead of “urban maintenance and construction tax”

First, China should set up the ecological compensation tax by legislation, the tax with the natural protection resources, pollution tax, and other related tax, build the environment tax law system for China. Natural resource tax mainly includes the existing resource tax, consumption tax, cultivated land usage tax, urban land use tax and vehicle tax, and other tax with the function of environmental protection; Pollution tax mainly include air pollution tax, water pollution tax, solid waste tax and noise pollution tax, discourage the behavior of the pollution of the environment; Other taxes, such as value-added tax, income tax from the design of the preferential tax system to protect ecological environment. The purposes of ecological compensation are ecological environment protection and promote the harmonious development between human and nature, based on the ecosystem service value, ecological protection development cost, opportunity cost, by means of government and market, regulating the interests relationship between ecological protection stakeholders.[4]

Ecological compensation adjusts the interests between the beneficiary and impaired people, so, the beneficiaries should be the taxpayer. From a legal perspective, the beneficiaries of ecological compensation include country, the enterprises and institutions and individuals. These beneficiaries who get the development and utilization of ecological environment and the negative externality of the environment, this section can be achieved by reform and perfect the existing resource tax, consumption tax, cultivated land usage tax, urban land use tax and so on to achieve the purpose of gathering ecological compensation; For those beneficiaries enjoy the good ecological environment, because of others (especially in poor areas) sacrifice development opportunity to protect the

ecological environment, we can achieve the purpose of gathering ecological compensation by establishing ecological compensation tax .

Second, we should replace urban maintenance and construction tax with ecological compensation tax. Specifically, we should replace the urban maintenance and construction tax ecological compensation tax in China. Urban maintenance and construction tax is closely related to environmental protection tax, it is imposed in 1985, although a large part of the tax revenues for environmental protection of urban area, but from the point in time, they have a long history and not conform to the current economic development, it need to reform and serve the value added tax, consumption tax and business tax as the tax basis, it will expand the subject of tax scope, accords with the special nature of the ecological compensation tax. Based on tax revenue legal doctrine principle, China should formulate “interim regulations on ecological compensation tax”, make the detailed rules about the subject of tax, tax calculation basis, tax rate, tax collection and administration and so on. The current urban construction tax only levy tax on domestic enterprises and individuals, but exclude foreign-invested enterprise, foreign enterprises and foreigners. It cause the unfair tax burden of domestic and foreign enterprises, the tax subject should include ecological compensation, unit of domestic and foreign enterprises and individuals. The urban construction tax is a kind of additional tax, it has very strong dependent. Because of the small scale urban construction tax revenues and income instability, it weaken the function that urban construction tax in raising funds and protecting the environment. [5] it is a good idea that serve value added tax, consumption tax, business tax and income tax as the tax calculation basis for ecological compensation tax for, at the same time, we should increase tax rate, to ensure its function. Ecological compensation tax should be the central and local shared tax, earmark a fund for its specified purpose only. Central tax is responsible for involving two or more than two provincial-level administrative region ecological compensation, local tax responsible for provincial administrative region ecological compensation.

Setting up the tax differentiation system of ecological compensation

Tax preference is an important policy tool, it is also a kind of effective means of ecological compensation. The central and western regions in China are often the rich resources and environment areas, they play “ecological security”, “resource reserves” and “landscape construction” role in the national development, but at the same time, it is lagging economic development and poverty area, they need compensation from benefit region or rich crowd, in order to balance the interests of all parties. Therefore, we should establish a conducive to ecological compensation tax differentiation system, especially set up the different preferential tax policy from the eastern region. In order to promote the effective implementation of the regional ecological compensation, we can take preferential tax levy measures to these areas；water conservation area, flood storage area, soil conservation area, windbreak and sand-fixation and biodiversity conservation area，the measures include tax reduction, duty free, tax reimbursement, tax credit. It can increase financing ability of regional ecological compensation from tax incentives, and guarantee the sustainable supply of good ecological environment.

Abstract. In the course of sports meeting, managing large amounts of data by hand is very difficult, the computer will be used in sports meeting management, accuracy and efficiency of data processing provides an important safeguard, in this paper, the sports meeting information system analysis and design. First, workflow analysis, pointed out the modern sports meeting work flow, as the basis for the next software development work; Then, functional requirements analysis, modeling example through interaction with each participant to clarify the main functions of the system implementation; Finally, the framework structure design, design the SSH three layer frame structure based on J2EE, for the presentation layer, business logic, data access layer is described in detail. To study the content of this article is based, easy to construct, easy maintenance, good reusability Web systems.

Introduction

The sports as the basis of various sports, occupy the important position in competitive sports, has a wide range of mass. Various schools usually have to be held annually, is to improve and test the health of students and teachers, to carry out an effective way to national fitness campaign. Organization of sports would be a complex and careful management, in particular arrangement, recording, announcements, many things to attend to, workload is big,]input of manpower, material resources, financial, and low efficiency, error prone [1]. Large amounts of data by hand are very difficult to manage, easy to go wrong. The computer will be used in sports meeting management, accuracy and efficiency of data processing provides an important safeguard. Currently, most universities have constructed a fast, advanced and applicable campus network, to achieve a collaborative management of internal campus teaching, research, communication and office, to enhance the overall level of the school information technology, to improve the school research, teaching efficiency. Sports meeting as an important part of school work, should also give full play to the role of the campus network. Therefore, will build sports meeting information system, to service in the whole process of the sports meetings, to achieve efficient, convenient, fast handling in the Sports information, is the future development trend.

Workflow Analysis

Sports meeting work is divided into three stages, namely the organization before, during, and after the data management and statistical analysis [2,3]. Workflow is shown in Fig. 1.

(1) The management before sports games. The School Sports Organizing Committee to develop competition rules, including the date, venue, race project, faculties and departments participated grouping, enrollment and limit the number of items reported faculties, admission ranking and awards, extra points; Organizing Committee among the departments issued sports meeting notice and competition rules; departments race project registration; The organizing committee according to the enrollment of each department, make the game schedule; The organizing committee print order book and various forms such as race schedule, team player information table, items grouped tables and others; The school issued the order book to each department.

(2) The management during sports games. The contest judges according to the competition situation truthfully record score; determine whether there is need for the final project, if necessary,

in accordance with the competition rules to screen out the final list, according to preliminary results are allocated the runway by the rules, and print the final notice; For the final project, after recording results, in accordance with competition rules to determined the obtain ranking athletes, and according to the project integral rules, the corresponding integration accumulated will add its units, print transcripts of the project contest for publicity.

(3) The management after sports games. All entry competition results carrying on the statistics, summary, calculate each class and each unit of the total scores (including athletes score, score, score of spiritual civilization score, manuscript scores and other extra points) and announce the results; athletes to the sports meeting with the previous sports meeting results and other sports scores compared to see whether the record-breaking situation. If there is, and the timely report to the chief judge and approved; finishing print out all the achievements and the sports meeting -related information, to facilitate the Organizing Committee announced at the closing ceremony. And data archiving and backup.

Fig. 1. Workflow analysis on sports meeting

Functional Requirements Analysis

The use case model is used to describe the designated system use cases, actors, portfolio cases — relationship with the participants. Use case modeling using the Unified Modeling Language (UML), UML is the beginning of an OMG standard in 1997, is a software system to support the development of modeling and graphical languages, providing modeling of all stages of software development and visualization support, including from the requirements analysis to the specifications, the structure and configuration. The use case model of the system is shown in Fig. 2, the interaction process of each participant is described as follows:

(1) Organizer: The main work includes the information release, venues and equipment management, data statistics and analysis. Information published by the website, including competition rules, game schedule, race project, registration, grouping and distribution runway conditions, individual performance, group performance, and others; venues and equipment on site for unified planning, unified distribution, unified management, in order to keep the competitions running smoothly; according to game data generated various reports, report data will be distributed to the relevant athletes and personnel, the relevant data for analysis and comparison, drawn sports meeting organizing successful experience.

(2) Staff [4]: The main work include registration management, grouping and distribution runway, performance management. Each participating units reported statements after checking into the computer system; according to registration, race project and game schedule, for track and field competition events grouped, for race project distribute runway, organized competitions official program, and in accordance with the actual situation, the order of the game be adjusted accordingly; The race results and names entry the system, provide timely results and ranking and other relevant information to the organizers.

(3) Athletes, referees and the public: do not have the data input, modify, delete function, can only query relevant information. Can query the sports rules, competition rules, the competition arrangement, organization, equipment space, registration, grouping and distribution runway, competitions official program, individual performance, group performance, individual nominations, ranking, and others.

(4) Administrator: The main work is to maintain the system, including network systems management and software system maintenance. Network systems management is mainly to design, installation, configuration, management and maintenance the network equipment and server systems on the whole network. To do technical guarantee for the safe operation of the internal network [5]. Software system maintenance task is to correct software systems in the course of discover the hidden errors, expand the new function and performance requirement by the user in the course of the use, its purpose is to maintain the normal operation of the software system.

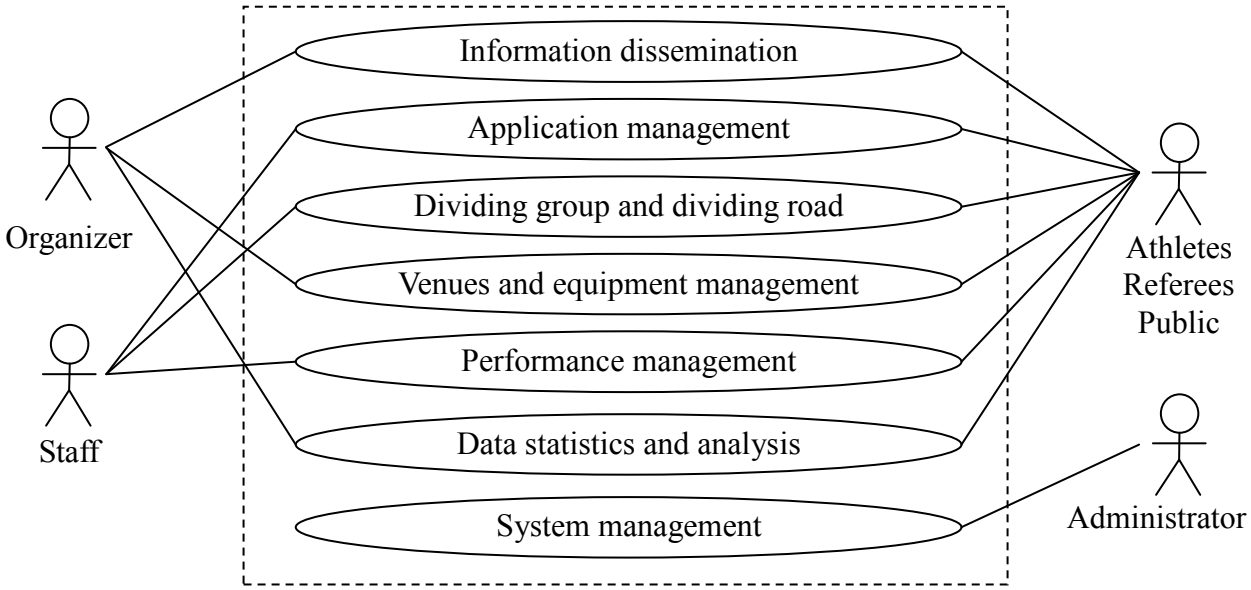

Fig. 2. Use case model on sports meeting information system

Framework Structure Design

Software framework is a set of related abstract model, used to guide large-scale software systems in all aspects of design. Software framework is a systematic sketch, is based on certain principles, from a different perspective on the various parts of the component systems to match and arrange, the formation of the system which consists of a number of structural framework, including the various components of the system, externally visible properties of components and relationships between components. From a business oriented software framework to transformation oriented technology, with shorter development cycles, improve software quality, reduce software costs, easy to modify and maintain. SSH is an integrated framework of Struts+Spring+Hibernate, is currently one of the more popular open-source Web application framework that helps developers build a clear structure in the short term, can be a good reusability and easy maintenance of Web applications [6-8].

SSH framework of basic business processes are: the presentation layer, first through the JSP page to implement interface, is responsible for receiving the request and send a response, then the Struts according to the configuration file (struts-config.xml) and to ActionServlet received Request delegate to the corresponding Action deal. In the business layer, Spring IoC container of managed service components is responsible for Action providing business model components and collaborative object data processing components to complete business logic, and provides transaction processing, buffer pools and other container components to improve system performance and ensure data integrity. In the persistence layer, depending on the object of the Hibernate mapping and database interaction, processing the requested data of DAO component, and returns the processing results.

Conclusion

The purpose of this system analysis and design is to develop a set of suitable for athletics information management system, and services in the sports meeting organizers, staff, athletes and referees, To facilitate the exchange of information between the audience and the manager, is conducive to improve the sports quality, efficiency and the management level. Workflow analysis pointed out the modern sports meeting organizing workflow, which is based on the demand analysis, pointed out the main function of the system; design the SSH three layer frame structure based on J2EE, easy to construct, convenient maintenance, good reusability the Web system. In the development and use of the process should pay attention to the following questions [9]: The sports meeting in repetitive and complex work is processing the standardized management of system; adapt to the development of today's information age, improve work efficiency; ensure the fairness of the sports meeting, fairness for athletes; reduce the work intensity of the sports meeting staff, save the sports meeting holding cost.

Green Management of Tourist Attractions region under the Background of Circular Economy

Feilong Liu

School of Economics and Management Hunan Institute of Science and Technology, 414006,Yueyang, Hunan, China

E-mail:07302982@163.com

Keywords: circular economy; Tourist Attractions region; green management

Abstract. Circular economy is a new theory to realize the win-win of economic development and environment protection in the mid- to late 19th century ,and is a basic way to achieve the sustainable development of economic and social. Circular economy of tourism should be strictly follow the 3R principle of"Reduction, recycle and reuse"of circular economy .For the management of traveling scenic areas, it must carry out the green management effectively , so as to achieve the purpose of low consumption, low emissions and high efficiency.Therefore,we must establish firmly the new concept that to develop circular economy in tourism areas;to full carry on the management of green tourism ;and to strengthen the joint efforts that have traveler to participate in.

The basic concept of tourism circular economy

Circular economy is a new theory to realize the win-win of economic development and environment protection in the mid- to late 19th century ,and is a basic way to achieve the sustainable development of economic and social.This paper try to introduce the theory and method of circular economy to the tourism industry, not to study the six big elements that eating, living, traffic, travel, shopping and entertainment, but to study the concept and development pattern that develop the circular economy tourism.During the study, we mainly studied and discussed the basic path of circular economy carried on tourism scenic areas,In the view of the tourism industry, circular economy tourism should be mainly refers to creating value by carrying on the standard of services,that is to say,to realize the sustainable development of tourism,we should consider to eliminate or reduce the direct and indirect negative effect that the tourism enterprises and tourists on the tourism environment as much as possible, from designing product and development of tourism service to the whole traveling. Circular economy of tourism should be strictly follow the 3R principle--"reduction, recycle and reuse"-- of circular economy. Following the law of ecological development for all tourism economic activity,to realize feedback cycle process between resources and renewable sources(products)in the tourism resource development and tourism activities, in order to achieve the purpose of reasonable development, efficient utilization and minimum pollution, the clean production, comprehensive utilization of tourism resources, tourism, ecological design of tourism products and tourists the sustainable consumption,and to make the tourism economy system can harmoniously incorporate into the material circulation process of the tourism system in the end.[1]

The basic ideas of building circular economy in Tourist Attractions region

Under the guidance of the circular economy theory , the minor cycle of tourism enterprise demand we should establish a best link in the most economic objectives and the best environmental objectives, according to the concept of eco-efficiency,and by the common behavior that support the sustainable development.And scenic spots as a individual tourism management unit,which is engaged in the operation and management activities, is the core products of the tourism destination , also is the main research object and the important part of tourism circular economy .According to the concept of circular economy tourism, circular economy in the tourism scenic areas can be understood as the minor cycle in the level of tourism enterprises .Therefore, it’s necessary that

managers of traveling scenic areas should consider the development of tourism enterprise in the long run.they must adopt cleaner production technologies, reduce the use amount of tourism resources as much as possible, minimize or avoid human activities causing the abuse and destruction of tourism resources,and environmental pollution and ecological disturbance and destruction to the traveling scenic areas ,so that not only can ensure the ecosystem and attractive of the scenic spots, but also can constantly improve their ability for the development of circular economy,to realize the sustainable development of tourism scenic areas .circular economy in scenic spots included the usage of tourist resources in the stage of development and planning of the scenic area, control and governing the environmental pollution in the phase of tour, and waste recycling.In tourism scenic areas development process, bringing much joy to the tourists ,and bringing economic benefits to the local, negative impact should be reduced to a minimum in the development of local tourism ,that's to say, carrying the effective green management in the tourism scenic spots, so as to achieve the purpose of low consumption, low emissions and high efficiency.[2]

The basic path of carrying out green management in Tourist Attractions region under the background of circular economy

Firmly establish new ideas of circular economy in Tourist Attractions region

Ideas guide behaviors.Circular economy developed in the tourism scenic areas set up the new system, new resource outlook, new consumption and benefit must be based on the basic theory of circular economy and tourism, and combined with the actual situation of tourism scenic spots.For example,the beneficial outlook of the traveling scenic areas require to balance the relationships between the good social benefits and ecological benefits in the development of tourism resource.In terms of economic benefits, both the development of tourism resources and a tourism investment project, must study its feasibility at the first,carefully analysis investment benefit and constantly promote the development of tourism resource and add the economic benefits of tourism project investment, which is material conditions to ensure the sustainable development of the tourism industry.In terms of social benefit,it should be consider the level of local economic development when developing tourism resources and designing tourism products,and considering people's psychology to bear.In terms of the ecological environment benefit,it should be guided by the principle of reasonable use of tourism resources and meet the requirements of environmental supporting capacity,to promote environmental protection by development,and to improve the comprehensive benefits of development by environmental protection, so as to form the virtuous circle of the protection and development,and create harmonious ecological environment benefits.[3]

Full implementation of green tourism management

It is no doubt that promote and implement is first to develop circular economy in the tourism scenic areas.Government is the main power to of promote circulation economy in the tourism scenic areas.it is hard to imagine that the circular economy of the scenic areas can develop without government's leading and participation .Only by the government to formulate the scenic area in the development of circular economy development plan and policies, can effectively guide and promote green management of tourism enterprises.So,there are some work should be follow:

(1) Do well the plan and follow-up soft management.According to the characteristics, the first thing need to do is planning well of tourism scenic spots.Tourism development must adhere to the principle of "planning before the development, protection premier and careful development" , and emphasize the importance of ecological environment evaluation, planning, protection and construction management, strict enforcement of the environmental impact assessment system, strengthen evaluation and analysis to the impact on the environment, ecological and tourism carrying capacity.After the plan, the soft management to the management of the tourism industry should highlight .So-called soft management is refers to the government create a social environment to create conditions to support enterprise, or by means of administrative legislation and decrease the negative effects of development,and make the enterprise complying with the consumer trends, making environmental production, promoting sustainable development of business in the market system rather than by administrative means to intervene in the tourism business activity.Soft

management must first to pollution-free new energy, saving energy resources to replace non-renewable or harmful to the environment resources.

Second, the government should give policy on environmental protection product development, production.On the fiscal taxation and credit to give discount.Advocate green, the protection of resources, environment quality and human health, and meet the demand of green consumption and services.

Finally, construct the environmental protection enterprise culture construction.Environmental protection enterprise culture system requirements specification staff daily behavior, coordinate the enterprise benefit, social benefit and tourists benefit relationship, to balance the social ecology.[4]

(2) Developing green technologies and establishing green evaluation system. Developing circular economy in tourism scenic areas should follow the technical ideas to reduce the tourism consumption in the process of resource consumption and pollutants and emissions by the analysis of the logistics of tourism system .Building tourism green technology system is the precondition and key of developing circular economy in the tourism scenic spots .The green technology system including pollution control technology to eliminate the pollutants, recycling technology for recycling waste,clean production technology that is no wastes or less wastes to make green products,which can realize the waste minimization in production process by he implementation of the green technology.In the development process of scenic areas, it also need to actively promote the usage of clean energy, the development of energy-saving facilities,the standard implementation of the green hotels,the sewage treatment of hotels and scenic areas , and adopting gray water recycle technology , the construction of ecological trails, the construction of anhydrous ecological toilet, the protection of the natural river scenic spots, the control of air pollution in scenic areas,the restoration of vegetation and the engineering implementation of wildlife conservation, etc.On the basis of the traditional tourism, applying the principles of ecology,design the structure and function coordination, system optimization, benign operation of ecological tourism system.Working out relevant technical standards and specifications,constructing the evaluation system of development of circular economy in scenic spots.Circular economy in tourism scenic areas is a part of circular economy, cycle tourism economic development not only pursue the tourism economic benefits and the growth of benefits,but also more to highlight the protection and construction of tourism environment, showing the ecological implication, bringing higher spiritual enjoyment to tourists.Thus, to promote the development of circular tourism economy in scenic areas, must change the current tourism economic development level of the inspection way, that's to say , emphasizing on economic benefits, at the same time, strengthening the resources development and utilization of per unit of GDP, the level of recycling resources, tourists evaluation indicators such as pollution, tourism environmental bearing capacity, thus to develop circular tourism economy index into the tourism economic development appraisal system.Of course,formulating appropriate evaluation system according to the different tourism scenic spots resources characteristics and development status, index to reflect economy and green.[5]

(3)Actively guiding green consumption. Tourism consumption occupies an important position in the social and economic development, tourism products or services only after being final consumption can realize its value.Therefore, the most important link is advocating green consumption policy is to build a tourist scenic spots of circular economy .the concept of green consumption is generalized, it has three meanings: one is to advocate consumption not contaminated nor green tourism products to help the public health.Second, paying attention to in the process of consumption of garbage disposal will cause no tourism environment pollution;third is to guide consumers to shift consumption concept and pay attention to save tourism resources and energy and change the unfavorable way the public consumption of the environment .

(4) Try to develop green ecological education and promote development of circular economy in tourism scenic spots by ecological education.Ecological education is especially important in the circulation economy development of tourism scenic areas , is a major part in ecological tourism software operation, also the differences with the traditional tourism.It mainly includes: setting up the environment education infrastructures in tourist areas, such as to establish a scientific

explanation boards beside the landscape ecological environment ,signs remind passengers pay attention to the clean environment and environment waste boxes , etc.;using multimedia technology to make tourists accept of environmental education through various channels, such as add ecological knowledge and points on tickets, tourist map for attention, etc.;adopting the appropriate means of punishment, guide tourist to green habits and behaviors;distribute waste collection bags printed with "ecological tourism "must return the recycling of in the scenic spots for tourists ;advocating visitors to plant trees or memorial trees for conference in the appropriate place , and improving awareness of the participation of tourists.Tourism colleges and universities should open or strengthen courses about ecological tourism and protection of tourism environment, to strengthen the students' environmental knowledge and environmental awareness.Green consumption is the locomotive of promoting circulation economy in tourism scenic areas, it is only through ecological education, could better guide the public to actively participate in the green consumption, the concept of circular economy in the traveling scenic areas is deeply rooted in the mind of the people.[6]

(5) Strict implementation of government regulations and local laws. Nowadays,China is lack of relevant legal norms about circular economy of tourism scenic areas.Therefore, to promote the development of circulation economy in the tourism scenic areas should should quicken the pace of making the law and system.Developing circular economy of tourism scenic areas involves various aspects such as society, economy and environment, and need to establish an effective administration system and mechanism, and make the necessary laws and regulations, so that to immobilize the positive results .

Strengthening continuously the joint efforts participated by travelers

Implementation of circular economy in tourism scenic areas not only needs the advocacy of government and the self-discipline of enterprises, but also need to improve the social public participation awareness and participation ability.Tourism organizations and tourism enterprises at all levels have to widely publicize and guide to tourists so that they can actively support the local resources and environmental protection activities in the tourism activities, and to understand and respect as far as possible the local cultural and natural heritage, to prevent and stop the adverse effects on the tourism destination by taking some necessary measures ,to prevent and stop effectively the misconduct destruction of the ecological environment , and actively support green management activity of the scenic spots and the effective implementation of the sustainable development countermeasures.

Keywords: landfill gas, health risk assessment, exposure pathway, chemical contaminants

Abstract. Health risk assessment (HRA) methodologies of three stages of Municipal Solid Waste Landfill (MSWL), including operation period, maintenance and management period after closure, and usage period without any restricted limits were built in this paper. The major exposure pathways to environmental contaminants were considered: inhalation of gas and dust during operation period, and ingestion of four food pathways categories (plant foods, meat, milk, and fish), groundwater and dust during usage period without any limits. The endpoints of HRA of MSWL are individual lifetime carcinogenic risk for all the carcinogenic chemical contaminants, and hazard index (HI) for all the non-carcinogenic chemical contaminants to the landfill worker (only at the operation period), and to the public near to the landfill (at all the three stages) respectively. The parameter values of calculation model are conservatively chosen. This is the first time in China that an integrated risk assessment methodology for landfill gas and leachate is attempted to develop. HRA methodologies will facilitate rapid estimation of the risk level of MSWL.

Introduction

Health risk assessment is an important method of quantitatively assessing the risk for human health from contaminants released to or contained in the environment in which humans live. Gaseous and leachate are generated in the Municipal Solid Waste Landfill (MSWL). Gaseous contaminants can enter ambient atmosphere, and leachate can leach into groundwater, so the human health and the environment safety will be affected. The technical requirements of liner systems, monitor rules, and management guidance during closure period of the MSWL are determined in the Chinese Standard (Standard of Pollution Control on the Landfill Site of Municipal Solid Waste, GB16889-2008). The first stage, operation period, is concerned with air pollution. After operation period, the landfill site will not be released for usage until the contaminants concentrations in the leachate for the two successional years after closure period are below the concentration limits for the sampling and monitoring values of the leachate(e.g. 0.001mg/l for Mercury Contaminants; 0.05mg/l for Hexavalent Chrome; 0.1mg/l for Arsenic; and so on)[1][2].

The primary purpose of the Health risk assessment methodologies(HRA-MSWL) is to assist in the comparison of design alternatives for landfill, and to assess health risk from MSWL. Three parts of main contents are contained in HRA-MSWL: (1) Engineered barrier characteristics of MSWL. (2) Exposure Scenarios and pathway of HRA. (3) Health Risk Assessment.

Engineered barrier characteristics of MSWL

Landfill systems including various combinations of vegetation, cover soils, waste cells, lateral drain layers, low permeability barrier soils, and synthetic geomembrane liners may be modeled. The design of typical engineered barrier in China is monolayer impermeable synthetic membranes systems chose by HRA-MSWL. HRA-MSWL permits two or more barrier liners to be adjacent to each other. If a design has two or more soil layers adjacent to each other, All the layers would be expected to act as a single liner, and will remain nearly saturated and contribute significantly to the head loss and restriction of vertical drainage, then the depth of the two layers should be summed up and an equivalent saturated hydraulic conductivity should be computed for the combined liner.

The scalar parameters of the different liners, such as porosity, thickness, that is completely specified by its magnitude and has no direction, need to be summed up. Equivalent scalar parameters should be computed as the example of equivalent porosity of total barrier liners[3].

$$n = (n_1 d_1 + n_2 d_2) / (d_1 + d_2) \quad (1)$$

In the type: d_i(i=1,2)=the depth of i barrier liners, m. n_1, n_2 represents equivalent porosity of barrier liners 1, 2 respectively.

The vector parameters of the different barrier liners, completely specified by a magnitude and a direction, such as the equivalent saturated hydraulic conductivity, should be calculated in connection with direction. When the vector velocity of the water flow is vertical to the direction of the saturated hydraulic conductivity, the equivalent saturated hydraulic conductivity should be calculated as follows

$$K = \sum d_i / \sum (d_i / k_i) \quad (2)$$

In the type: K= equivalent saturated hydraulic conductivity, m/s. d_i=the depth of i barrier liners, m. K_i= the saturated hydraulic conductivity of i barrier liners, m/s.

When the vector velocity of the water flow is horizontal to the direction of the saturated hydraulic conductivity, the calculation method of the equivalent saturated hydraulic conductivity is the same as one of equivalent scalar parameters. The synthetic membrane liners are layers of nearly impermeable material that restricts significant leakage to small areas around defects. Leakage is computed to be the result from two sources: manufacturing flaws (pinholes) and installation defects (punctures, cracks, tears). Leakage rate of impermeable synthetic membranes can be determined by choosing experimental values. Before unlimited usage period of landfill sites, the volume of the seepage through the contaminated zone, Q_L, can be calculated by[4]

$$Q_L = A \times K_s \times \frac{d + h_{max}}{d} \quad (3)$$

In the type: K_s = equivalent saturated hydraulic conductivity, m/s. d = the equivalent depth of all barrier liners, m. A = bottom areas of landfill, m^2. h_{max} = hydraulic head above the barrier liners, m.

After unlimited usage period of landfill sites, the volume of the seepage through the contaminated zone, U^s is given by

$$U^s = I \times A \quad (4)$$

In the type: I = the infiltration rate of the seepage, m/a. A= the surface area of the contaminated zone, m^2.

The exposure assessment assumes a private well downstream of the source. This well is conservatively assumed to be so close to the source that no dilution with groundwater that has not been impacted by the source takes place. The transport modeling of the contaminants in the aquifer does not consider dispersion or diffusion effects. This is also a conservative assumption. The contaminants concentration(C_i^w) in the well water is given by the dilution with the groundwater volume (U^{gw}) flowing underneath the area of the contaminated zone:

$$C_i^w = \frac{U^s \times C_i^s}{U^{gw} + U^s} \quad (5)$$

$$U^{gw} = z^{gw} w^{gw} v^{gw} p^{gw} \quad (6)$$

In the type: U^s =the volume of the seepage through the contaminated zone, m^3. U^{gw} =the groundwater volume flowing underneath the area of the contaminated zone, m^3. C_i^w = the i contaminants concentration in the well water. C_i^s = the i contaminants concentration in the seepage, mg/m^3. z^{gw}= the thickness of the aquifer, m. w^{gw}= the width of the contaminated zone perpendicular to the flow of the aquifer, m. v^{gw}= the pore water velocity of the groundwater, m/a. p^{gw}= the effective porosity of the aquifer.

Exposure Scenarios and pathways of HRA

Exposure pathways

During the three stages of MSWL, there are some exposure scenarios and pathways by which contaminants can migrate from the source to a human exposure location. An inhalation pathway consists of two segments: (1) an airborne exposure segment linking the source (contaminated zone) with the airborne contaminants and (2) an inhalation segment linking the contaminants with the exposed individual. The inhalation segment is characterized as follows:

$$CDI = \frac{C_a \times I_a \times EF \times ED \times BA}{BW \times AT} \tag{7}$$

In the type: *CDI*=the average daily contaminants intake by inhalation, per unit body weight mg $kg^{-1}day^{-1}$. C_a=the pollution concentration in the inhaled air mg/m^3. I_a=inhaled gas rate m^3/h. *EF*=the exposure frequency h/d. *ED*=the exposure duration during lifetime a. *BW*=body weight kg. *AT*=the average time affected by contaminants d. *BA*=biological available factor, usually equal to 1.

When reference concentration (RfC) or Unit risk factor(URF) is in existence, the risk can directly be assessed by the product of the pollution concentration in the air and RfC/ URF.

The ingestion pathway categories include food pathways (plant foods, meat, milk, and aquatic foods), soil ingested, and drinking water. The plant food pathways category only choose the plant which can take in contaminants by root uptake from crops grown in the contaminated zone, and simultaneously by foliar uptake from contaminated irrigation water. The aquatic food pathway is for ingestion of fish. The average daily contaminants intake CDI is

$$CDI = \frac{C_{food} \times I_f \times EF \times ED}{BW \times AT} \tag{8}$$

In the type: C_{food}= the contaminant concentration in the plant food(mg/L), soil(mg/L), or drinking water(mg/m^3). I_f= ingestion rate of food (I_f, kg/a), soil (I_s, g/a)or drinking water (m^3/a). The other parameters are similar to the formula 7.

Dermal intake of contaminated soil or water: body surface can take in some contaminants when contaminated soil or water is contacted. The average daily contaminants intake CDI is soil:

$$CDI = \frac{C_{as} \times SA \times AF \times ABS \times EF \times ED \times BA}{BW \times AT} \tag{9}$$

water:

$$CDI = \frac{C_w \times SA \times PC \times ET \times EF \times ED \times BA}{BW \times AT} \tag{10}$$

In the type: C_{as}= contaminant concentration in the soil mg/m^3. C_w= contaminant concentration in the water mg/L. *SA*= body surface areas contacted with soil or water cm^2. *ABS*= dermal absorption factor, conservatively equal to 1. *AF*= dermal retardative factor mg/cm^2. *PC*= dermal penetrating factor, conservatively equal to 1. The other parameters are similar to the formula 7.

Air concentration calculations

Air concentration calculations are performed for area source for annual average meteorological conditions (D stability class, 1.5m/s average wind speed) using the formula 11[5].

$$C = \frac{Q}{\pi U \sigma_y \sigma_z} \exp\left(-\frac{H_e^2}{2\sigma_z^2}\right) \tag{11}$$

In the type: *C*=ground contaminants concentration at the downwind distance x(m), mg/m^3. *Q*=release rate of gas contaminants, mg/s. *U*=wind speed at the release height, m/s. σ_y=horizontal diffusion coefficient, m. Applicable to the leeward distance of 0~1000m, σ_z=vertical diffusion coefficient, m, Applicable to the leeward distance of 0~2000m. H_e=average height of the release of the area sources, m.

Horizontal and vertical diffusion coefficient σ_y, σ_z are estimated using the formula12 and formula 13 respectively. Horizontal diffusion coefficients, σ_y, are affected by sampling time span, especially when the sampling time span is more than 10mins, so need be corrected by formula14. Usually the calculated concentration is in connection with the sample time span of 30mins to the air pollutions. So the contaminants concentrations of the instantaneous landfill gas will be corrected by formula 15.

Wind speed at the release height U is calculated by formula 16.

$$\sigma_y = 0.143940x^{0.926849} + \frac{a_y}{4.3} \tag{12}$$

$$\sigma_z = 0.126152x^{0.838628} + \frac{H_e}{2.15} \tag{13}$$

$$\frac{\sigma_{y,30}}{\sigma_{y,t}} = \left(\frac{30}{t}\right)^q \tag{14}$$

$$\frac{C_t}{C_{30}} = \frac{\sigma_{y,30}\sigma_{z,30}}{\sigma_{y,t}\sigma_{z,t}} \tag{15}$$

$$U = U_{10}\left(\frac{\mathrm{H_e}}{10}\right)^{0.15} \tag{16}$$

In the type: a_y=the length of the area source on the ordinate(y-axis), m. U_{10}=wind speed on the height of 10m, m/s. U=wind speed at the release height, m/s. H_e=average height of the release of the area sources, m. x=the distance from the centre of the area source to the potential receptor location, m. C_t=ground contaminants concentration at the receptor location for the sampling time t, mg/m^3. C_{30}=ground contaminants concentration at the receptor location for the sampling time 30mins, mg/m^3. $\sigma_{y,t}$,$\sigma_{y,30}$=horizontal diffusion coefficient for the sampling time t, 30mins respectively, m. $\sigma_{z,t}$,$\sigma_{z,30}$=vertical diffusion coefficient for the sampling time t, 30mins respectively, m. q= time dilution factor, for 0.17~0.5, usually equal to 0.2. t= the sampling time span of MSWL, 10mins.

Finally, ground contaminants concentration at the receptor location for the sampling time span 10mins, C_{10}, is corrected by formula C_{10}=1.25C, C=ground contaminants concentration at the downwind distance x (m), mg/m^3.

Landfill gas output, Q_m

The major components during natural decomposition of materials deposited in landfills are CO_2 and CH_4. CH_4 is considered over 20 times more detrimental to the atmosphere than CO_2. There are many trace components in the landfill gas, including volatile organic components(VOCs).

$$Q_m = \sum_{i=1}^{n} 2kL_0M_i \cdot e^{-kt_i} \tag{17}$$

In the type: Q_m=Maximum output of landfill gas, m^3/a. L_0= biological methane potential (BMP), m^3/t. k=rate constant of methane production, 1/a. M_i= waste amounts in the unit i landfill, tonne. t_i= time span from beginning of gas production to assessment point, a.

Health Risk Assessment

For substances presenting risks other than cancer, a Hazard Quotient (HQ; analogous terms include “exposure ratio” and “hazard ratio”) will be derived as the ratio of the estimated exposure (for each critical receptor) to the toxicological reference values for risk characterization (RfD) or tolerable reference concentration (RfC), as follows[6]:

$$HQ = \frac{CDI}{RfD} \tag{18}$$

$$HQ = \frac{C}{RfC} \tag{19}$$

In the type: HQ= the comparison of the levels of chemical contamination at the site to levels that are known to cause harm, dimensionless. CDI= average estimated exposure per kg body weight per day, mg/kg/day. RfD= the toxicological reference values for risk characterization, mg/kg/day. C= chemical contamination concentrations in the ambient medium, mg/m^3. RfC= the tolerable reference concentration, mg/m^3.

HQ for individual exposure pathways should be presented where there are pathway-specific toxicological reference values. Where exposures via multiple pathways are being summed for comparison to a single RfD (for example, it is common to sum oral and dermal exposures for comparison to the oral RfD), it is necessary only to display the HQ for the summed exposure.

For substances deemed to be carcinogenic, the estimated exposure will be multiplied by the appropriate slope factor (SF) or unit risk (URF) to derive a conservative estimate of the potential incremental lifetime cancer risk (R) associated with that exposure. R is derived as[6],

$$R = CDI \times SF \tag{20}$$

$$R = C \times URF \tag{21}$$

In the type: *CDI*= average estimated exposure per kg body weight per day, mg/kg/d. *SF*=the appropriate carcinogenic slope factor, $(mg/m^3)^{-1}$. *C*= the concentrations of air-borne contaminants, mg/m^3. *URF*= unit risk value of air-borne contaminants, $(\mu g/m^3)^{-1}$.

Where pathway-specific slope factors or unit risks exist, the risks via inhalation and the risks via oral plus dermal exposure should be estimated separately. In other cases, the cancer risks posed by simultaneous inhalation/dermal/oral exposure will be estimated.

Conclusion

An integrated risk assessment methodology for landfill gas and leachate is attempted to develop for the first time in China, and conservatively facilitates rapid estimation of the risk level of MSWL. Health risk assessment (HRA) for landfill gas combines gas output with air concentration calculations by simplifying program and choosing parameter values. HRA for landfill seepage connected landfill engineered barriers with water and pollutants migration during the whole life span of landfill by simplifying program and choosing parameter values conservatively. The major exposure pathways to environmental contaminants were considered: inhalation of gas and dust during operation period, and ingestion of four food pathways categories (plant foods, meat, milk, and fish), groundwater and dust during usage period without any limits. The endpoints of HRA of MSWL are individual lifetime carcinogenic risk for all the carcinogenic chemical contaminants, and hazard index (HI) for all the non-carcinogenic chemical contaminants to the landfill worker (only at the operation period), and to the public near to the landfill (at the all the three stages) respectively.

The primary purpose of the model is to assist in the comparison of design alternatives for site selection and landfill engineered barriers, and to assess health risk of the different design alternatives. At the same time, the model will improve environmental impact assessment methodology having been universally used nowadays.

Keywords: Mercury (Hg), Content, Variation, Vertical, Jiaozhou bay.

Abstract. Based on the investigation data of mercury (Hg) in both surface and bottom waters in Jiaozhou bay in 1979 to 1981, this paper tried to analysis the vertical variations of Hg contents, and to reveal the transfer processes of Hg in the bay. Results showed that, Hg pollution in the bay is mainly discharged from the major rivers, the seasonal variations of Hg content in surface waters showed a similar trend in different years, with an order of spring (or summer) > autumn. The Hg contents in bottom waters were mainly determined by the sedimentation of Hg from surface waters. There were major three transfer processes of Hg as, 1) Hg from various pollution sources was transported to streams by rainfall, 2) Hg in streamflows was discharged to surface waters of the bay, and 3) Hg in surface waters was sedimented to the bottom of the bay.

Introduction

With the rapid development of social economic, atmosphere, lands and waters have been polluted by various pollutions. Jiaozhou Bay is located in south of Shandong Peninsula, which is one of the "frontier" of Chinese Reform and Opening, as well as an economic development region, has long been suffering from environmental pollution problems. Previous studies showed that this bay had long been suffering from both point and non-point sources pollution, and pollutants such as benzene hexachloride, petroleum hydrocarbon, and heavy metals had reach certain levels [1-11].

Hg is one of the one of the most critical environmental pollutants, with characteristics of high toxicity, bioaccumulation, and persistence. In previous several decades, Hg has been widely used in chloro-alkaline industry, plastic industry, electronic industry, metallurgical industry etc., as well as agricultural pesticide [12-13]. Based on the investigation data of Hg in waters in both surface and bottom Jiaozhou bay during time periods of 1979 to 1981, this paper tried to analysis the vertical variation of Hg in Jiaozhou Bay, to reveal the transfer processes of Hg, and to provide basis for pollution control.

Material and method

Study area. Jiaozhou Bay is located in the south of Shandong province (35°55′-36°18′ N, 120°04′-120°23′ E), and is around by economic developed cities such as Qingdao, Jiaozhou and Jiaonan etc. (Fig. 1). The total area and average water depth the bay is 390 km^2 and 7 m, respectively. This bay is typically a closed bay, whose bay mouth is only 3 km width. The main rivers are Haibo River, Licun River, Baisha River, Dagu River, Yanghe River, and Loushan River, all of which have seasonal hydrological features, and are transfer cannels for pollutants into the bay [1- 3].

Data source. The data was provided by North China Sea Environmental Monitoring Center. The measurement methods of Hg in water samples was follow by The Chinese National

Specification for Marine Monitoring (1991) [14]. The survey as conducted in May, August and November 1979, June, July and October 1980, April, August and November 1981, respectively. We defined April, May and June as spring, July, August and September as summer, and October, November and December as autumn, respectively.

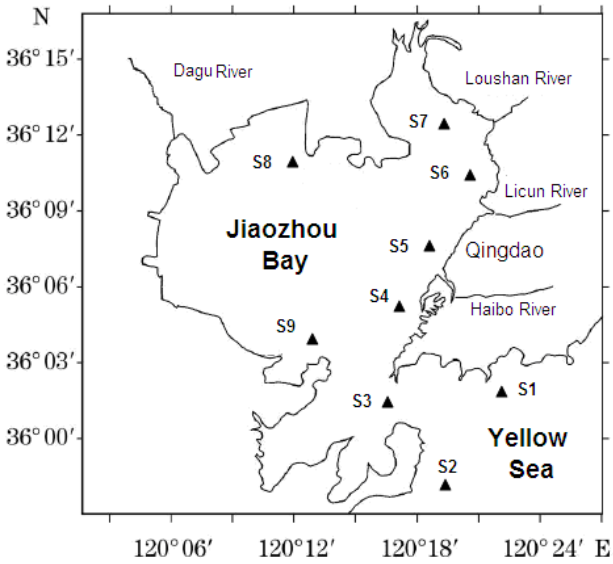

Fig. 1 Geographical location and sampling sites of Jiaozhou Bay

Results and discussion

Hg content. The Hg contents in surface and bottom waters in spring, summer and autumn in Jiaozhou bay were listed in Table 1[4-5, 8]. The seasonal variations of Hg content in surface waters showed a similar trend in 1979, 1980 and 1981, with an order of spring (or summer) > autumn. The reason is that the Hg pollution to the bay is mainly discharged from the major rivers, whose streamflows are mainly impacted by precipitation, which is concentrating in spring and summer. By comparison, the Hg contents in bottom waters had no significant seasonal variations, but increased with the increase of Hg content in surface waters in the same season. That's because Hg in bottom waters are mainly determined by the sedimentation of Hg from surface waters. However, in case of large input of Hg in spring (or summer), as in year of 1981 (Table 1), Hg content in bottom waters also showed an order of spring (or summer) > autumn. This trend indicated that Hg contents from surface waters to bottom waters decreased with time within the year due to the sedimentation of Hg in waters.

Table 1 The Hg contents in surface and bottom waters in spring, summer and autumn in Jiaozhou bay/μg.L^{-1}

		1979	1980	1981
Spring	Surface water	0.110-0.460	0.003-0.030	0.028-2.086
	Bottom water	0.030-0.140	0.002-0.007	0.029-3.125
Summer	Surface water	0.030-0.040	0.011-0.045	0.001-0.040
	Bottom water	0.020	0.002-0.029	0.002-0.026
Autumn	Surface water	0.010-0.020	0.010-0.030	0.002-0.017
	Bottom water	0.010-0.050	0.013-0.090	0.003-0.005

Hg transfer processes. Based on the vertical variations of Hg, we could draw a framework map to demonstrate the transfer processes of Hg in Jiaozhou Bay (Fig. 2). Fig. 2 clearly revealed the major three transfer processes of Hg as, 1) Hg from various pollution sources was transported to streams by rainfall, 2) Hg in streamflows was discharged to surface waters of the bay, and 3) Hg in surface waters was sedimented to the bottom of the bay. Previous studied showed that, Hg content in surface water of this Bay were always very high in waters close to river mouths of the major rivers, and showed decreasing trends with the flow directions [4-5, 8]. However, having in mind that the bay is a closed bay, the horizontal diffusion of Hg in surface water could be considered as but not the major transfer process.

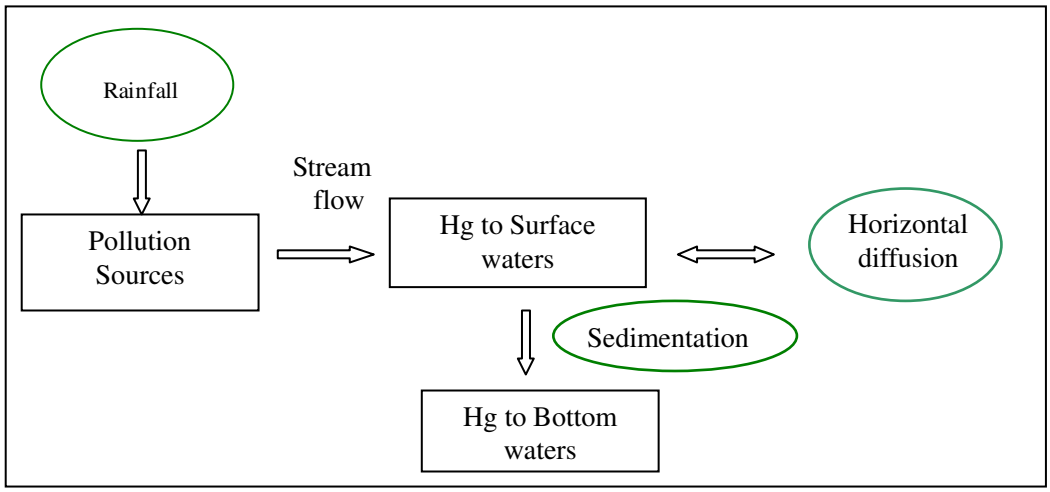

Fig. 2 The Schematic diagram of the waters transfer process of Hg.

Summary

Hg pollution to the bay is mainly discharged from the major rivers, the seasonal variations of Hg content in surface waters showed a similar trend in different years, with an order of spring (or summer) > autumn. The Hg contents in bottom waters were mainly determined by the sedimentation of Hg from surface waters. There major three transfer processes of Hg were, 1) Hg from various pollution sources was transported to streams by rainfall, 2) Hg in streamflows was discharged to surface waters of the bay, and 3) Hg in surface waters was sedimented to the bottom of the bay.

Keywords: Student Attendance System; Java EE; B/S Structure; Development of Mobile Terminal

Abstract. In this paper, according to the actual students management work in the school, and link to the student attendance work, we propose one design of the B/S structure system of student attendance management based on the Java EE framework. The system realizes performances such as request and approval leave online, students' attendance data summarize, and others which reduce the workload of student management and improve the working efficiency. With the rapid development of mobile network on campus, this system also has carried on the development of mobile terminal, to further expand the scope of application of the system with the desktop of the student management system transplantation.

Introduction

Student attendance work plays an important role in the student management. As well the attendance statistics are key reference data to undertake the student comprehensive assessment by employers or teachers. With the rapid expansion of network communication technology and the campus network engineering, the networkalization of student attendance system becomes a trend for better real-time performance, more convenient way of management to greatly reduce the workload of teachers and student management personnel, improve the work efficiency and save a lot of cost[1][2].

This paper fully carries on school student attendance system and researches the users type and operating scope of the system. According to the demand analysis, this paper designs the student attendance management system, and uses the Java EE framework to realize the system including performances of completing the background management, requesting for leave online by students, viewing hierarchically and level permission for student notes by teachers, as well statistical attendance rate of the whole term, and generate attendance reports, and so on[3][4][5].

As the development of the Internet technology and the computer technology, information technology is deeply affecting people's life. The development of mobile Internet, especially the third generation (3G) technology, it provides a powerful bearing channel and rich professional ability supports and makes the people's life more colorful. People also eagerly hope that they can browse the web to get information at anytime, anywhere and any place through the wireless network. But the mobile equipments have small screen, small memory, low bandwidth and other weakness that cannot compare with PC, so an abbreviated version of Student Attendance System is designed in the paper also.

Design of the Student Attendance System

According to system analysis, student attendance system is divided into four main kinds of users, students, teachers, students management, system administrator, as shown in Figure 1. Therefore, this system depending on the type of user will be divided into four modules, background management module and student module, teacher module and student management module.

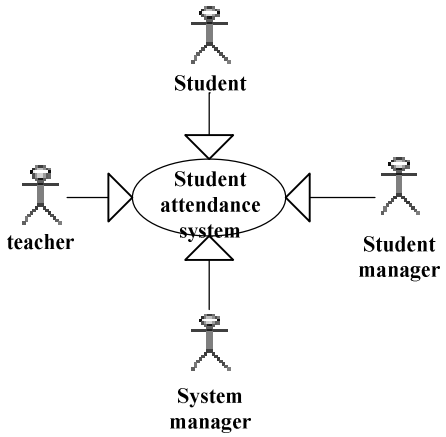

Fig.1. The Students Attendance System

For students, it is inevitable to ask for leave because of the various causes. For a long time leave request, it may even need the counselor of students submit for approval to the competent department. For general teachers, they need to checkroll of students, and assessment the final grades with average attendance. For the head teachers or counselors, besides the daily students' attendance situation, and leave approval, they also need make the final comprehensive evaluation reference attendance statistics of the students.

So, provided the specific function of this system mainly includes the following aspects:

1) Function to modify the personal information: all the system users can modify their personal information.

2) Query function: through the system, students, teachers, and administrators can query and related attendance information, and personal information. Such as the classroom teachers can just see they filled in, but can't query information filled by other teachers; while the head teacher can query a certain period attendance information of the class he charged.

3) Leave request functions: students can directly submit leave request online to the head teacher or counselor.

4) Checkroll function: mainly for logging in the system by classroom teachers, they can check who are absence in the class, and record the attendance for students.

5) leave approval function: the head teacher or counselor has approval right of one day's leave, in case of leave time out of one day, the superior manager’s approval right is needed.

6) data statistics function: teachers can get the absence of information of certain period or all time which include approved leave and truancy, and export the data to EXCEL table.

7) background management functions: each administrator can manage the background, such as add or delete information of students, class, teachers and others. But the general administrator has default access level 2, that means, he does not have permission to add, modify, delete the administrator. Only administrator with access level 1 can modify the administrator information.

The Framework of Student Attendance System

The implementation of this system, which is based on the field test of campus network and demand analysis for the function of the students attendance system, finally established the system goal. Depending on resources of campus network (see Figure 2), the system adopts B/S three layer structure of the data processing, in order to realize the workflow service and maintenance of all kinds of information query and permissions management, it integrates the attendance system and business system effectively[6][7]. The software framework of this system based on JAVA EE and database technology, combined Ajax technology, SQL Server 2000 as the backstage database, build a suitable school student attendance management system.

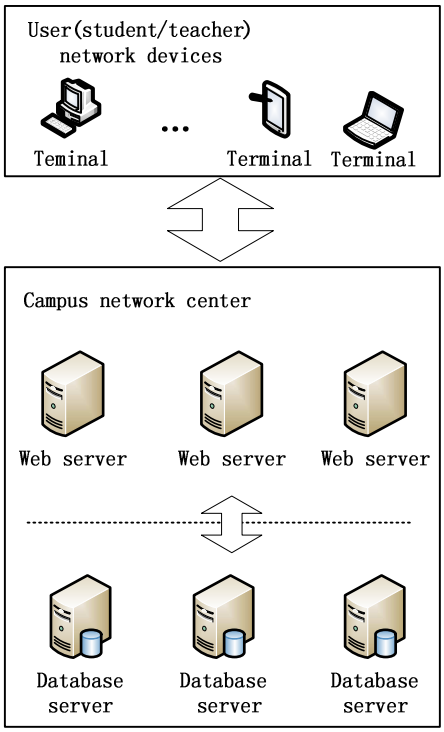

Fig.2. Campus's network resource

For students and faculty, this system is high frequency used so that it is requested simple interface and friendly operating. The class attendance statistics interface of this system is shown in Figure 3. The user just need simply click on the navigation bar on the left to switch each function.

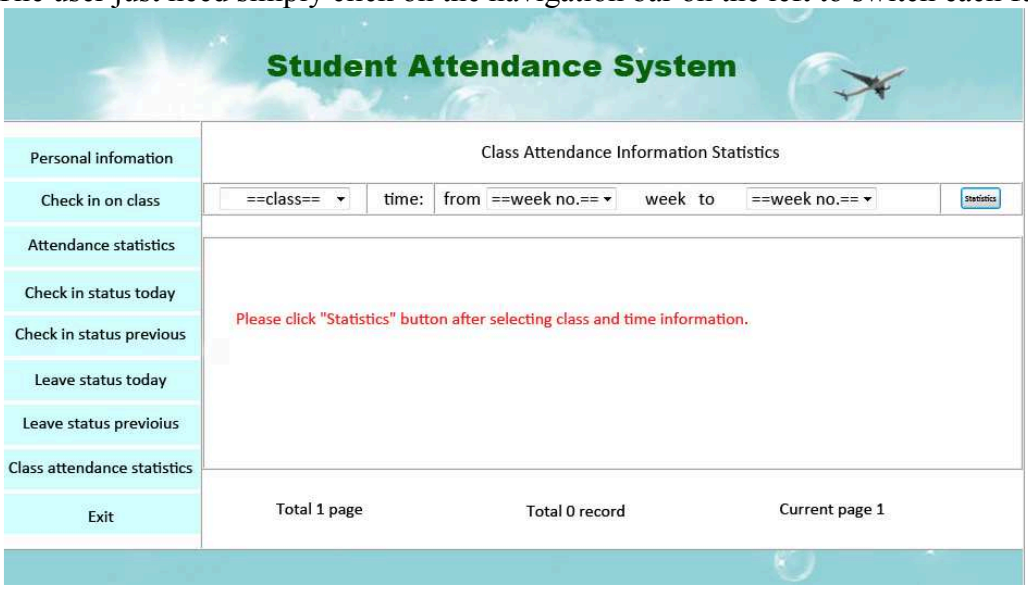

Fig.3. Interface of class attendance information statistics

Mobile client development

In recent years, with the rapid development of mobile communication technology and the expansion of smart mobile terminals, mobile Internet business steps into a golden period. Moreover, Campus life follows fashion trends tightly that almost all teachers and students own their smart phone. This provides the prerequisites for the student attendance system using in mobile terminal. But due to the mobile terminal screen is usually small, processing power is weak, so the functions of this system on the mobile end are selected.

This system mobile terminal classifies function according to user type as well:

1) students can login, write for leaving, check approval status;

2) teachers and staff can log in and view the leave request, approval and record attendance

And mass data requirement functions such as batch query, attendance statistics function are removed, which are only available in the desktop system.

Conclusion

The student attendance system was designed and implemented based on the campus attendance requirements. The system menu enabled different functions depending on the type of users to convenience for the user. For the same user with different levels of authority, provides the system data security. By the practical operation indicates that the system has high convenience, good fault-tolerance performance and certain economic practicality.

Although PC has been popular for teachers and students to deal with attendance process on campus, smart phone penetration is also reckoned because of small volume, easy to carry, more convenient for the teacher roll call at any time. So this system is applied to mobile client identification at the same time with reasonable cutting of the functions to make the design of a web page on the mobile device can be easily used.

Research on Design of Modern Warship Networked Fighting Simulation System

Yan-Hui Wang, Jian-Zhou Mao, Zhi-Hong Xiu

Dept. of Operation and Command, Dalian Naval Academy, Dalian 116018, China

bagum908@sina.com

Keywords: Warship; Network; Fighting Simulation; Agent

Abstract. The simulation system of the overall system structure and function module are established, on the basis of the analysis of designment of modern warship's networked fighting simulation system, the solutions of network architecture and Agent construct are provided., some key problems are discussed for the realization of a simulation system. There is a certain reference value for the construction and research of warship network fighting simulation system.

Introduction

Modern warship is an integrated fighting system, which makes use of the network technology, shares combat information resources through coordination between units under the same mission control among each fighting unit of the warship. Its simulation system is an important tool for the study of warship combat system operation mode, information process, and the command process. The study of warship network fighting simulation system from the design concept, system structure, and key technology has important guiding significance for modernization of warships, organization and command for each unit of the cooperative engagement.

Summarize

The study of complex systems is the foundation of modern warship networked fighting simulation system design. At present, there are two main types of research methods in complex systems. The first method is trying to establish an individual from the individual behavior of the complex systems isomorphism of microscopic model[1], its basic idea is that the characteristics of the complex system are extracted according to the individual model of complex system, find out the relationship between the individual and the interaction; then, running system in the certain synthetic environment, observe the system of macroscopic overall behavior through individual interaction. The second method is trying to establish a complex system from macro level and to constitute complex system of the whole behavior model. Its basic idea is that the evolution process of the overall behavior system is studied and analyzed from the angle of macroscopic overall. This kind of situation does not need to establish a system model under the level of individual subsystems and their relationship, but, the basic ideas of feedback control theory and methods are introduced in the process of building some methods. The typical theory includes of system dynamics method, the influence graph model, neural network and integrated.

On the design concept, modern warship's networked fighting simulation system, should be especially emphasizes the complexity of network simulation object and the whole system compared with traditional warship combat simulation system. Networking of simulation objects bright the system unit problem such as the change of aggregation depolymerization and efficiency calculation [2]. Modern warship simulation has a finer granularity of networking combat simulation system. The degree of information of old warship combat system is relatively low, its basic fighting unit includes detecting equipment and weapon system, and the basic fighting unit of modern warship not only includes detection equipment, weapon system, but also C3I system, it makes the whole combat capability of the warship combat system greatly improved, and gives the restructuring ability between different units to strengthen. Therefore, the simulation design should consider fully the simulation

object granularity, aggregation restructuring ability. At the same time, the research calculation on warship combat efficiency of the system as a whole should be strengthened in terms of system effectiveness calculation, on the basis of single weapon efficiency is given priority to in the traditional calculation.

The complexity of the whole system mainly includes the complexity of the simulation object, the complexity of the system function and so on. As the simulation object of modern warship combat system, it is also a complex system, the bottom-up approach should be highlighted in the study of its collaborative, network architecture, design and implementation of agents.

According to the above design, modern warship networked fighting simulation system should have the following main features:

First, input and output driven by dialogue, use windows graphical user interface in the front desk, and allow opening multiple documents view;

Second, using object-oriented c++ source code library, facilitates the secondary development of end user or analyst;

Third, chart integration and decision-making based on the operational environment adaptability of dynamic;

Fourth, environmental associations and user defined Agent behavior;

Fifth, each unit has a communication link;

Sixth, having the department and the overall warship dynamic controllers;

Seventh, with data collection and visualization tools.

The overall structure of the system

To supporting different application requirements, the modern warship combat simulation systems adopts hierarchical service oriented architecture, the architecture of the simulation system is shown in figure 1.

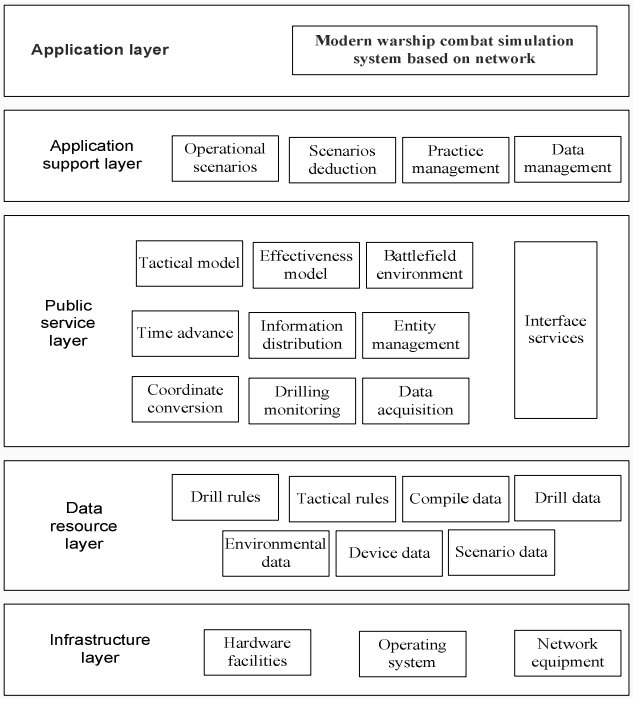

Fig.1The overall structure of the system block diagram

The infrastructure layer mainly includes computer and network devices for simulation, storage devices, input and output devices, and form a complete set of software, to provide the experimental environment support for completing the simulation task.

The data resource layer provides server and the mass storage device as the carrier, to store and manage the simulation experiments of all kinds of data resources, including the experimental plan, the test data, to set data, tactical rules, environmental data and equipment, etc.

The public service layer is the core of the framework, it provides a variety of public services for the system, mainly including the tactics model service, efficiency calculation service, time management, message distribution service, entity management service, coordinate transformation, the simulation monitoring service, data acquisition, and data interface services (to provide a wide range of standard data communication protocol interfaces).

The application support layer provides auxiliary tool module for performance analysis of combat simulation system of modern warship network, including test management module, scenario deduction module, scenario institution module, data record module, etc.

Function modules of the system

The realization of system function consists of seven sub modules, they are communication simulation module, environment simulation module, virtual force module, simulation management module, scenario compile module, scenario deduction module and record analysis module.

The communication simulation module is mainly to provide simulation system with high reliability of tactical communication system simulation support. In contrast to the old warships, one of the main characteristic of modern warship is its highly degreed information sharing network, its internal communication system including a digital network of combat system, video network, program-controlled telephones, etc. At the same time, information sources of warship combat are various, that also needs external communication system, including shortwave, ultra short wave communication system, satellite communication, data link, etc. Therefore, we should focus on its impact of communication simulation of difficult system network architecture and operation during the simulation, such as a result of damage caused by the topology structure of dynamic change. At the same time, factors of the complex electromagnetic environment of real time injection should be considered, and it should support receiving the interference of data from external module (such as the electromagnetic environment simulation module or control system), real-time calculate the influence of channel bit error rate by interference, which reflects the degree of communication interference[3].

Main function of the environment simulation module is to provide a consistent sea condition, weather condition, and electromagnetic environment conditions for simulation. Simulation object mainly is the modern warships and hostile forces, therefore in the environment simulation module, simulation environment factors, such as temperature, pressure, flow, wind, visibility, cloud and mist, all kinds of electromagnetic environment information, reef, drilling platforms and geographical environment and so on, should be outstandingly emphasized, which shows more influence on the warship than others entity.

The virtual force module mainly simulates detection equipment, command and control system, weapon systems, such as combat unit of the warship. Operations, such as information reconnoitering, auxiliary decision-making, arms controlling, weapons, electronic countermeasures, ship maneuvering, and so on, are driven by the combat mission. In a word , virtual force mainly include passive reconnaissance equipment, warning radar, tracking radar, all kinds of naval gun, the anti-ship missile, ship to air missile, torpedo, acoustic equipment, charge system, enemy's virtual force is mainly responsible for foreign warships, aircraft, missiles, etc.

The simulation management module is mainly responsible for experimental nodes, system parameters configuration, data acquisition planning, etc. It is also responsible for the test node time synchronization, to control and manage each operation node in the process of the simulation and estimate the ending conditions of the simulation, controls the test process according to the combat situation.

The scenarios compile module is a battle plan generating module. It is a supportively module used to determine the ship maneuvering under different operational conditions for command personnel and technical personnel on the basis of the battlefield environment and providing the initial conditions for man-machine confrontation simulation.

The scenarios inference module is mainly used for the dynamic deduction of scenarios, and tested the rationality of the battle determined elements, operational settings, etc.

The data recording module is mainly responsible for man-machine confrontation or the factor of forces in the process of deduction, such as the state, the location, the damage situation and interactive information recorded on both sides. It also could provide real-time both forces battle damage with curve, diagrams, tables, and so on.

Key technology of the system

The design of network architecture and Agent is the key technology of modern warship networked fighting simulation system, it is the critical factors of system structure and operation rules, and it is an important role to the system develop, it also is the foundation of the system overall design and key.

Network architecture

The network architecture of the system should not only solve the seamless link between elements, but also meet the end-to-end real-time transmission of information. In addition, the initial planning, network parameter settings and injecting should be more convenient, more shortcut. The network set up time is short, if the network structure changes, routing must adaptive dynamic adjustment, global topology does not have a significant impact when local network changes.

The establishment of the network architecture must accord with battle needs, adhere to the objective reality of modern warships, which requires the network structure should have a reasonable span and hierarchical structure. The span refers to the quantity of the domination unit of transverse department. The hierarchical structure is divided in longitudinal command level. Therefore, the studying of modern warship networked fighting simulation system should emphasize the benefits of span and hierarchical structure of modern naval combat system. Based on complex network theory, the WS network has the characteristics of the small path length (small-world features) and larger aggregation coefficient (polymerization features), as a result, network architecture of the modern warship networked systems can be conducted on the basis of the WS model[4]. Figure 2 is a modern warship combat system, the basic component of each unit in the network architecture symbols and coordinates are listed in table 1.

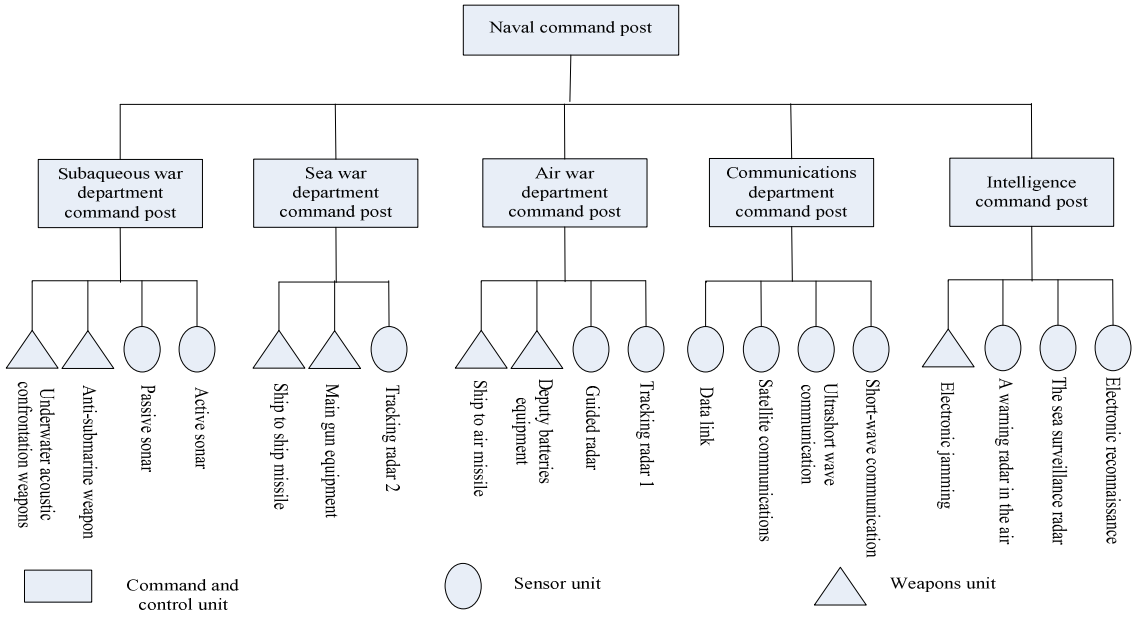

Fig. 2 The combat system of modern warship

Table 1 Each node code and coordinate

Node name	code	coordinate	Node name	code	coordinate	Node name	code	coordinate
Naval command post	JZ	(3.0, 3.0)	Electronic reconnaissance	GR	(1.0, 4.4)	Tracking radar 2	GL2	(5.2, 4.3)
Intelligence command post	QB	(2.2, 2.9)	Short-wave communication	DB	(2.4, 5.4)	Main gun equipment	ZP	(5.4, 3.5)
Communications department command post	TX	(2.7, 3.7)	Ultrashort wave communication	CDB	(3.1, 5.5)	Ship to ship missile	JJD	(5.5, 2.7)

Air war department command post	DK	(2.7, 2.2)	Satellite communications	WT	(3.9, 5.3)	Active sonar	ZSN	(5.2, 1.9)
Sea war department command post	DH	(3.6, 3.5)	Data link	SJL	(4.6, 4.8)	Passive sonar	BSN	(4.7, 1.2)
Subaqueous war department command post	DQ	(3.5, 2.5)	Tracking radar 1	GL1	(1.7, 0.8)	Anti-submarine weapon	FQ	(3.5, 0.5)
Electronic jamming	ZC	(1.6, 5.1)	Guided radar	YDR	(0.7, 2.1)	Underwater acoustic confrontation weapons	SK	(4.1, 0.7)
The sea surveillance radar	HJJ	(0.6, 3.6)	Deputy batteries	FP	(2.5, 0.5)			
A warning radar in the air	KJJ	(0.5, 2.9)	Ship to air missile	JKD	(1.1, 1.4)			

Design of Agent

Agent design is another key factor of the simulation system. Describing the agent need to establish entity model, behavior model and mathematical model. The entity model is mainly to describe each Agent levels, functions, components, equipment parameters, and to define the data type and scope, for the convenience of programmer's understanding; Behavior model is to define a set of the main Agent behavior rules, this need to list the action conditions, action termination conditions, structure and implementation process, action interactions, action data and structural description. Mathematical model is used to convert all kinds of behavior interaction to mathematical model, it is advantageous for the technical personnel to change the behavior of the structured rules into code execution. Among the three model, behavior model is the basis of Agent operation. Figure 3 is a naval gun unit behavior rules example, hence one can see that, clear Agent operating rules can be provided for developers from the figure description through rules, it solved the communication problem between military experts and technical experts.

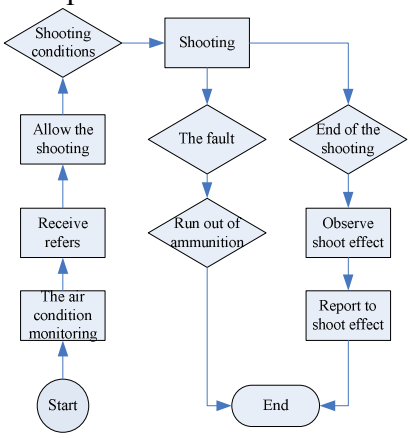

Fig. 3 The deputy artillery unit （Agent）fire behavior model

Conclusion

This paper analyzed the characteristics of modern warship networked fighting simulation system, system structure and function modules of the system are constructed, two key problems of the network architecture and the agent building are solved. The design of the simulation system is according to the development trend of modern warship networked fighting simulation system, it could well solve the problem of the construction of modern warship simulation system. This paper has a certain practical significance to deeply research warship network warfare and promote modern warship's operation ability based on information system.

Application of Reusable Framework Technology on the Workflow System

Chunyan Xue

Xiamen University Tan Kah Kee College, Zhangzhou, Fujian Province, 363105

xuegirlxcy@sina.com

Keywords: Reusable Framework; Workflow System; Application

Abstract. Focus on workflow task duplication of information processing in the interface of the show, interact with applications and other complex technical difficulties, the paper design and implement tasking reusable framework technology, to enhance the flexibility of workflow system, while reducing the complexity of the task processing , in order to carry out the system development and maintenance. Establishing a common framework for the design task processing, to process basic tasks, task processing applications each parameterized configuration variable part, by explaining the configuration items, dynamically generated parameters interface and back-office services, so as to realize the application system and workflow platform universal interaction.

Introduction

Workflow system

Workflow is a model that is used to calculate the flow of work, which is a set of logic rules can organize works together, create an appropriate model and calculate the workflow. The main problem workflow solutions are: to achieve a business goal, among several participants, according to some predetermined rule using the computer automatically passed documents, information or tasks.

Core functionality of the workflow is routing functions. The ultimate goal of workflow is to simulate the real business in software products. Workflow routing can be divided in serial routing, parallel routing, dynamic routing, condition routing accordance with the actual situation[1].

Workflow Management System, WFMS is a system which can define, create, execute the workflow. WFMS can provide functionality to support the following three aspects:

1) Construction function: its components for workflow process definition and modeling activities;

2) Operational control functions: manage workflow processing and schedule the staff in the work flow.

3) Operation and interactive functions: interaction function among WFMS and the user (participants or controller of the operational work) and external application program tools.

Currently, workflow products can better solve the task scheduling, process control and other functions, and reduces the c technology complexity of the process control in the project development process. However, these products do not summarize, abstract and encapsulate task process,. The WFMS does not well to reduce the application complexity of the task process. Reusable framework technology to use in the workflow system can solve these problems.

Reusable framework technology

Reusable framework technology separated the process control logic of business from the business logic. Then business logic is further broken down into the core business logic and assistant business logic assist. The core business logic is divided into relatively independent business components which reduced the workload of the application development, thus speeding up the system building.

When the system is running and process logic changes, reusable framework technology can redefine the process in order to adapt to changing business processes, Reusable framework technology make application system managed unified the business process[2].

Reusable framework technology summarized reusable tasking based on business requirements analysis, designed and implemented in a common design patterns. Using reusable framework technology, workflow system need not additional design components when dealing the tasks which compliance with reuse applicable conditions, adjust the configuration items to complete with reusable tasking.

Operation Mechanism of the Reusable Framework Technology

The existence of the enterprise business process reflects the production and the business process, which necessarily involves division and collaboration of the staff that are multi departments, and multi-role. Some business processes are a complex process which is cross-level, cross-regional, cross-quarter and span widely in space and time. Therefore, it is necessary to improve and abstract the common features of the business[3].

Reusable framework determined the core technology solutions according to the difference of the roles, the division of labor and conditions, including information transfer, general-processing tasks, flexible configuration of the task element.

Reusable framework consists of definitions, interpretations and running, consisting of the following main components: page template, configuration items, task processing UCC (ITaskUCC); page element generate service (IPageElementGenerateService); specific task background processing (IFrameworkEmbededService / IFrameworkEmbededFactory).

Reusable framework consists of definitions, interpretations and running, consisting of the following main components: page template, configuration items, task processing UCC (ITaskUCC); page element generate service (IPageElementGenerateService); specific task background processing (IFrameworkEmbededService / IFrameworkEmbededFactory).

Figure 1 is a schematic diagram of the framework of the overall operation of the mechanism. Tasking reusable framework uses a JSF framework. Reusable framework through JSF framework when processing HTTP requests through reusable framework to generate service interface elements, reusable framework defines the interface configurations and interface templates to interpret and generate tasking interface that provides human-computer functional interaction. Behavior in the form of human-computer interaction interface events, by control of UCC processing framework through the JSF framework, the UCC processing logic and relationship process logic of tasks and processing.

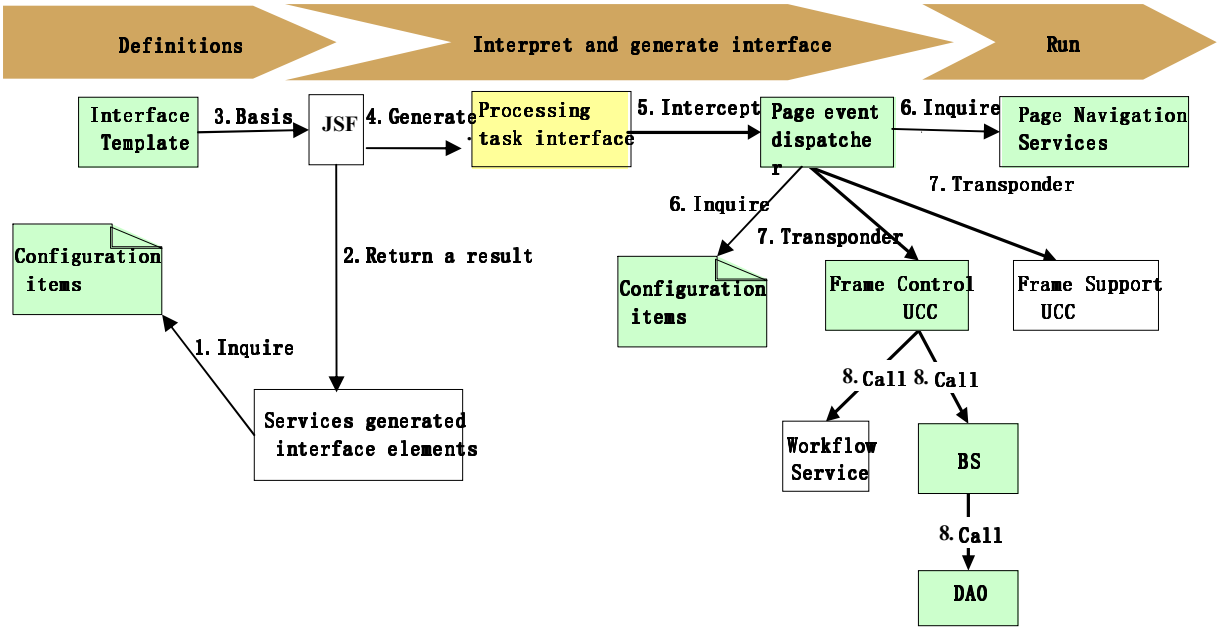

Fig.1 Framework operating mechanism

Page templates

Tasking need to define a page template for the realization of each frame, according to the page template definite the layout of the tasking page, the content of the page is divided into static definition section and dynamic generation section.

The static definition section refers to fixed and unchanging page elements that applied the scene of processing tasks in the framework

Dynamic part refers to that framework related services dynamically generated page elements. based on the contents of configuration items , status of the task and other elements.

Configuration item

Configuration item refers to the different parts due to the different attributes of tasks. The main role of the configuration item is achieved dynamically configurable portion by way of the parameters configuration in the page template and configurable information view. Reusable frame achieved configuration information based on the process tasking, the dynamic change portion is two-dimensional . Reusable frame show information's differences generated by attribute of each task. Reusable framework configured differences information content (elements of information) by way of configuration items. Reusable framework directly calls configuration items of information from the database.

Configuration items reusable framework can be divided into: critical data, supporting data, routing type, opinions conclusion specific task configuration items, business processing and document manipulation.

Critical data go to the process when the process starts, and may be modified in the process flow, so this type of data obtained during the execution of the process.

The items belong to a part of the property of the task that supporting data, the type of routing data, opinions conclusions identified in the course of the workflow definition. Data is obtained by querying the workflow definition in the course of process execution.

Read configuration items are responsible for the IConfig and as the base class for all configuration items tasking.

Tasks processing UCC（Use Case Controller）

Workflow system mainly consists of routing selection, personnel selection, job submission and other operations. Reusable framework abstracted a general-purpose processing from workflow tasks processing to form a tasks processing base class, All tasks processing inherited the base class can achieve task operation by way of the common application processing provided by the base class provides operations to greatly reducing duplication of development effort, and ensuring consistency of tasks processing.

ITaskUCC is the base class of all tasks processing UCC, It defines a set of common methods and properties of the task processing design. Each framework needs to define a tasking UCC and inherit the base class. UCC-tasking operation with processing tasks, such as pre-submit, submit, and other operations, in coordination with operation between IGeneralWorkFlowService and other background services.

ITaskUCCExtension is extension class of ITaskUCC, inherits ITaskUCC, is the base class for handling specific tasks.

Pretreatment specific task: needs to calibrate data or update flags before each task processing for a variety of business.

Page elements generation service

Configuration of the configuration items is reflected in the tasking interface, reusable framework provides page elements generated service class service as the base class for interface elements resolve to achieve configure page conversion.

Achieve Reusable Framework Technology in the Workflow System

Call workflow system applications

Workflow system applications are divided into "business units" and "Operation". Business units reflects what to do on an active node, the operation reflects the control authority in processing on this activity node, such as "approved", "rejected", "fight back" and so on. Business units and operations are certain types of applications, but to distinguish these two concepts that can help develop a application System which has smaller coupling and dependence on the process running . so that the development of the process is variable and easy to change. Formally, the business units can be called by the workflow engine, and the operating is called by system is he controlled method of the workflow engine by control to application system.

Task operations

The task operations in workflow system is operations of processing parts ,such as start the process, terminate the process, hangs the process, direct current, shunt (single handle) and combined flow (more than one person handling), joint trial, etc., in order to interference task processes freely, to achieve specific tasks independently.

Depending on difference of the task status, the persons who have different privileges of the tasks can perform the corresponding operation on the task, the state of the tasks changed accordingly after the operation. The relationship among of people, tasks and operations is not arbitrary. The relationship which are shown in Table 1 .

Table.1 Personnel Tasks Relational Table

Start	Operate	End	Permissions needed
Assigned	View	Assigned	Assigned Members List
Assigned	Claim	Claimed	Assigned Members List
Claimed	Complete	Completed	Claimant
Claimed and Assigned	Transmit	Assigned	Claimant
Claimed and Assigned	Cancel	Canceled	Administrator
Claimed and Assigned	Reassign	Assigned	Administrator
Claimed	Replace	Assigned	Claimant
Claimed and Assigned	Forced complete	Completed	Administrator

Processing tasks

The workflow system used of reusable framework technology is a real system of "man – machine", the user is the basic role of the system and the direct object of the task assignment. The operational staff can see the "task list" for themselves which the computer listed in and track the status of each task or continue a task . In order to the task processing of the reusable framework flow is able to implement in the organization "seamlessly", the project team must comply with the working methods which had already defined, practice identified and effectively, and must have measurable results at every stage. Task processing method as follows:

1) Create and assign tasks

When the users create a task, he must designate the owner to be the executor of the previous task executor unify. All task allocation algorithm is set to assign ToUsersAndGroups, all tasks must be claim and then perform. For general tasks, perform this task in my job list, the system automatically claim the task for the user when perform this task in my job list, complete the task only when the user submits tasks.

2) Task execution mode

Task execution mode decides the manner of the task which is performed during tasking operation. The three modes as follow:

First time: The first time you run the task in the process, you need to create and assign tasks;

Repeat: The task has been recreate and redistribute which had executed and completed previously, and the tasks are usually assigned again to the staff who had executed and completed the tasks;

Short: the tasks are no longer performed, and will be go to the next task directly.

3) Routing operation

Routing operation decide process execution path. The routing operations include: normal forward, return revision, return modify policy, wrong return, retrieve, supplementary materials, and so on.

Conclusion

Reusable framework technology of workflow system analyzes and abstracts the structure and composition of the actual business process, and divides the task processing into immutable part and a variable part. The technology achieves universal part of the task processing by building a generic model of reusable framework t. The reusable framework technology of tasking, reduced the complexity of application processing more quickly adapt to changing business requirements due to changes brought by the application processing of tasks.

Abstract. This essay explains the concept of System-wide Information Management and discusses the merits of implementing SWIM in ATM systems. And the essay also introduces the current situation of the SWIM development worldwide, especially in USA and Europe. Additionally, it illustrates SWIM related programs which is carrying on in China, and the promising future for SWIM development in China.

1 SWIM Introduction

SWIM is an abbreviation form of System-Wide Information Management. SWIM provides flight information to airlines, aircrafts, airports, air traffic control centers and other apartments associated with flight. It acts as a "system of systems" [1] to serve for information sharing, exchanging and management among all parts of the civil aviation.

Currently, the aeronautical information exchange pattern is end-to-end; different systems transmit data through different data interfaces. This makes the data transmission links huge and complicated. The new concept of SWIM abandons the traditional end-to-end pattern, collects all kinds of aeronautical information to a single terminal and all information users acquire data through the terminal. SWIM simplifies the traditional information transfer method greatly as fig. 1 illustrates.

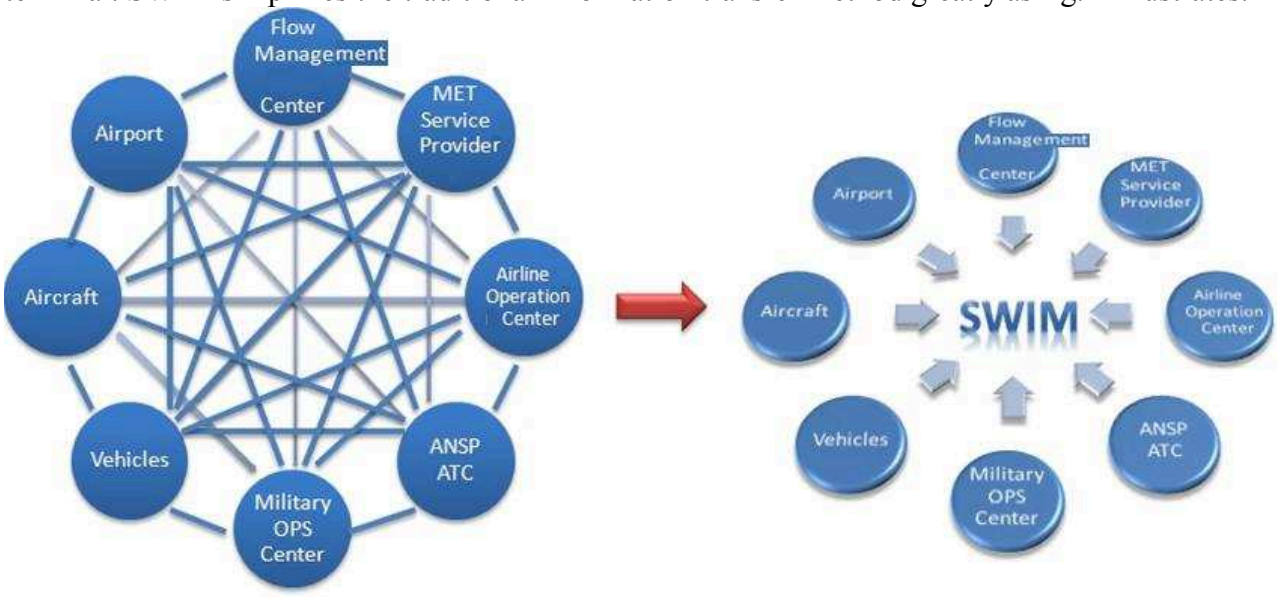

Fig. 1 The transition in exchanging aeronautical information

Implementing SWIM will bring various benefits. Initially, aeronautical information users like pilots, air traffic controllers and dispatchers can receive the same information to make appropriate decisions in order to improve the safety of civil aviation. Secondly, information sharing will enable the airspace users get information that may affect flight in time. In this case, it will enable better efficiency of airspace use. Moreover, SWIM will also improve the decision-making process and streamline information sharing for improved planning and execution. Ultimately, the information in SWIM concentrate in a common interactive terminal; it will save a large amount of constructing cost

of new interfaces and also save the maintaining fees of current interfaces connecting different systems.

2 SWIM Development Abroad

The concept of SWIM initially appeared in 1997, it was the concept of National Airspace System Wide Information Service (NWIS) which Federal Aviation Administration (FAA) presented. In 2001，Boeing Company put forward the concept of Common Information Network. Aeronautical Radio Technology Committee integrated NWIS into NAS concept in 2002. In the same year, FAA signed a contract with International Telephone and Telegraph Corporation (ITT) that ITT would design the functions and physical architecture for NAS. In 2003, ITT and FAA cooperated with each other and finished the basic function analysis and NAS-level requirement development. The work of study on the physical structure, transition selection and suggestion, structure simulation and acknowledgement were completed in 2004. Boeing Company and FAA worked together in 2004 and they defined the duty of SWIM under the framework of current and imagined NAS air traffic operation and communication system. In 2005, International Civil Aviation Organization (ICAO) also accepted SWIM concept in order to facilitate the information-based integration process of air traffic management. By far, Single European Sky ATM Research (SESAR) in Europe, Next Generation Air Transportation System (NextGen) in USA and Collaborative Actions for Renovation of Air Traffic Systems (CARATS) in Japan are all study on technologies related to SWIM.

2.1 SWIM in USA

NextGen is a concept which represents the American National Airspace System transferring from ground-based air traffic control to satellite-based air traffic management. It intends to develop programs and technologies which can operate more efficiently, SWIM included. SWIM provides authorized users with information to facilitate collaboration among different apartment in the NAS.

FAA develops SWIM in three segments. The first two segments are under development. On July 15, 2009 FAA Joint Resources Committee approved the development of SWIM segment 1. Segment 1 will last for 5 years and complete in 2015. The assignments are listed as follow [2]:

1. Implementation of a set of federated services in the NAS with SWIM-provided governance, standards, and software to support development of reusable SOA services;
2. SWIM provides requirements, schedule, and funding to seven SWIM Implementing Programs (SIPs);
3. Segment 1 results in services deployed to all Air Route Traffic Control Centers (ARTCCs), 39 Terminal Radar Approach Controls (TRACONs), the Air Traffic System Command Center, the William J. Hughes Technical Center (WJHTC), and NAS Enterprise Management Centers (NEMCs).

After the first segment accomplished, SWIM will equip with 9 capabilities which cover 3 areas including Aeronautical Information Management (AIM), weather, flight and flow management, as fig. 2 illustrates. The 9 capabilities are Special Use Airspace (SUA) Automated Data Exchange, Corridor Integrated Weather System (CIWS) Publication, Integrated Terminal Weather System (ITWS) Publication, Pilot Report (PIREP) Data Publication, Flight Data Publication Service (FDPS), SWIM Terminal Data Distribution System (STDDS), Flow Information Publication, Runway Visual Range (RVR) Publication, and Reroute Data Exchange. Up to March 2012, two capabilities, ITWS Data Publication and CIWS Data Publication, are complete and operational. Three capabilities are complete and waiting for installation, which are AIM SUA Automated Data Exchange, PIREP Data Publication, and Pre-Departure Reroute. And three other capabilities, STDDS, Flow Data Publication, RVR Data Publication, are on schedule and within budget allocation. FDPS has been replanned but is expected to be on schedule and within budget allocation.

In November 2010, FAA JRC approved to carry on the study on SWIM segment 2. This segment will last to the year of 2016 and the assignments are as follow [2]:

1. Continues provision of governance, standards, and software to additional NAS programs;

2. Implements enterprise messaging service (NEMS) for other NAS programs and facilitates transition by Segment 1 SIPs.

The core services in Segment 2 are messaging, interface management, security, and enterprise service management [3]. NEMS provides messaging service for SWIM Segment 2, and it is through Enterprise Service Bus that enable heterogeneous systems integrate together. There are 6 NEMS nodes which were already built till July, 2013. Interface management service includes interface specification, discovery, and schema management. Security service covers authentication, authorization, and audit services. And enterprise service management is service monitoring, service configuration, and system monitoring.

In 2012, SWIM enriched its concept level to four levels. The levels are FTI IP backbone, SWIM Messaging infrastructure, Standards for Data Exchange, and NextGen Application. The standards for data exchange are divided into three parts which are Aeronautical Information Exchange Model (AIXM), Weather Information exchange Model (WXXM) and Flight Information Exchange Model (FIXM). As three subprojects of SWIM, AIXM, WXXM and FIXM are all under development. The other key technologies of SWIM are aircraft access to SWIM (AAtS), cloud computing and so on.

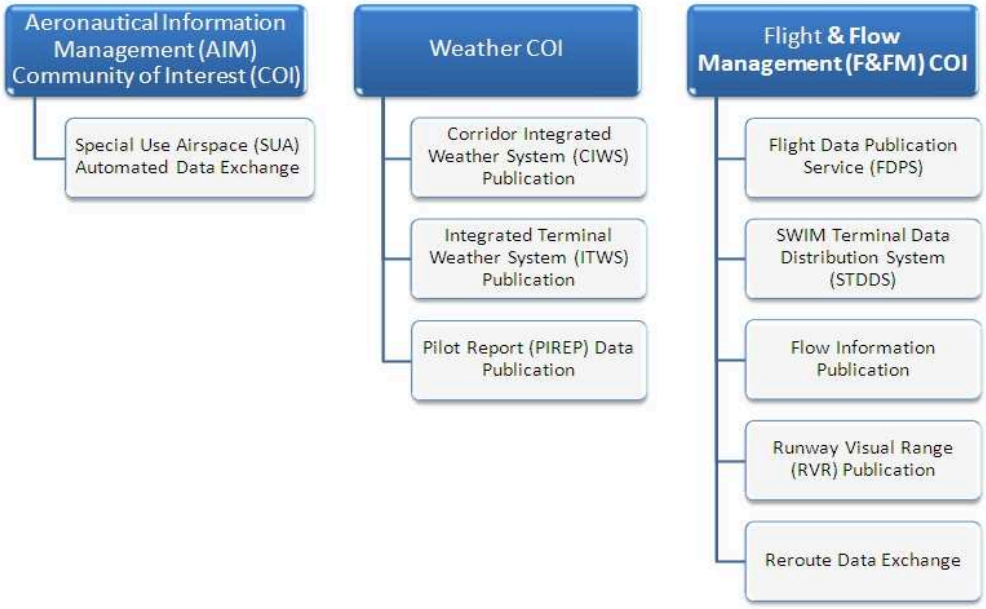

Fig. 2 The nine capabilities in implementing SWIM Segment 1

2.2 SWIM in Europe

From SWIM concept first appeared in Europe in1998, the following years SWIM was always mentioned in documents related to ATM. Considering lacking of systematic study on SWIM concept, there was no program aiming at SWIM. Not until March 2009, the overall ATM planning regard SWIM as a significant constraint in implementing SESAR that SWIM officially became a subproject of SESAR Joint Program which is commonly studied by departments related to ATM since then.

SESAR determined the operational concept of SWIM, which explains the definition, principles, the groundwork of transition, and the advantages in detail. Based on the principle of SWIM, SESAR will establish ATM Information Reference Model (AIRM) and Information Service Reference Model (ISRM), develop information management functions, put up SWIM infrastructure, and explore SWIM-based applications in the process of developing SWIM. AIRM offers consistent reference to other models so that the original meaning wouldn't change during information exchanging process and ensure the compatibility of semantic in ATM systems. Service-Oriented Architecture (SOA) is adopted when constructing the infrastructure of SWIM. In this way, newly built systems are connected with the old one. SESAR began to put the first step, prototype verification, into practice in 2012; the content of it are Flight Object (FO) allocation, publication and subscription of web services, and expanded NOP Business to Business web services [4].

SESAR work groups have two work packages concerning SWIM; one is information management (WP-IM) and another is SWIM infrastructure (WP-SI). WP-IM constructed the framework from information producers to information consumers, which is a management structure that includes all kinds of information management capabilities. WP-SI is in charge of the technical infrastructure of SWIM, which is used for dealing with data and services; it includes the common SWIM technical services which exchange information physically and adopts mainstream IT technologies.

2.3 Collaboration between USA and Europe

The Memorandum of Cooperation (MOC) between FAA and the European Organization for the Safety of Air Navigation (EUROCONTROL) for joint Research and Development (R&D) is in place for 26 years and work with each other will continue, especially between NextGen and SESAR R&D. In December 2009, FAA and SESAR JU had a discussion on the commonality, interoperability of SWIM. In November 2010, FAA and SESAR had another meeting discussing the roadmap and differences between each other in developing SWIM and figuring out the most suitable area for them to have a set of experiments. In April 2012, FAA and EUROCONTROL agreed a coordinated planning on SWIM interoperability. Currently, FAA-SESAR has 5 work groups. Work group 2 is focused on information management which includes SWIM interoperability, information management operability, and meteorological information exchange.

3 SWIM DEVELOPMENT IN CHINA

Given the fact that the air traffic grows rapidly in China and Asia/Pacific region [5], the emerging air traffic brings challenges to the current ATM systems. In China, we have launched several researches to cope with this situation, and hope to facilitate the informatization of our civil aviation.

In 2010, study on the SOA-based efficient mechanism of sharing ATM information, Guide of Science and Technology Project of Civil Aviation Administration of China (CAAC) [6], put forward the efficient information sharing and exchanging mechanism of SOA-based interoperable ATM data; it will allow all ATM systems connectively to each other and provide a synthesized information service. This program laid the foundation of SWIM construction in China. The contents of the program are SOA-based ATM information architecture, standardized interface management, messaging and security service, information sharing mechanism and prototype verification system.

In 2011, National Key Technology Support Program funded the project of Civil Aviation System-wide Information management technology and platform proposed by Beijing ATC Technology Corporation. The program designed the infrastructure of SWIM and analyzed the information sharing and exchanging technique. Moreover, this team cooperated with North China Air Administrative Bureau and built an experiment and assessment SWIM platform. In January 2013, during 2 years' study, requirement analysis, and development, Beijing ATC Technology Corporation successfully finished the initial construction of SWIM in North China Air Administrative Bureau Communication Network Center. The initial construction focused on installing the system server, network firewall, device end, connecting the network, and equipping the system with needed facilities. North China air traffic flow management system is the first system which accessed to SWIM system. In the future development, North China Air Administrative Bureau will construct connective platform with airlines' operation control center and airports to complete the SWIM system for information sharing and exchanging. In September 2013, North China Air Administrative Bureau held the new SWIM technique training class, it symbolized the SWIM system putting into use and test in China.

Regarding the twelfth national five-year planning as an opportunity, CAAC Air Administration Bureau applied for civil aviation integrated information service demonstration project. This project aims at popularizing the use of SWIM in the domain of civil aviation, so that the ATM, airlines' operation control center, airports and even military could share information with each other in order to realize collaborative decision-making and improve the air transportation capability and efficiency.

Because China hasn't study SWIM for that long, it develops SWIM with the help of international partners. During the year of 2010 and 2012, Chinese aviation specialists had five fruitful meetings

with FAA SWIM technician experts. Chinese professors learned a lot advanced experience in developing SWIM. And in June 2012, SESAR/SWIM international seminar was held in Civil Aviation University of China, it's a meaningful step for us to cooperate with SESAR. In December 2013, China Academy of Civil Aviation Science and Technology held EUCCAP-SESAR seminar. The Joint actuator governor of SESAR explained the up-to-date development of SWIM in SESAR.

Considering that SWIM concept is emerging in China and it is promoted all over the world, it is necessary for China to go further exploring this technique to make it operate in our ATM systems. And in order to act on international convention, there is a great possibility that China will also choose SOA to construct the whole SWIM system and use XML to transfer data across different interfaces. By far, SWIM has not been studied widespread, so SWIM (mainly its core models) will most probably act as a demonstration project in some local areas. Once the project makes any progress, it is promising for SWIM to develop in large-scale. The aim of developing SWIM is the same between China and abroad, but the situation of Chinese civil aviation facing is not alike. Firstly, the airspace is administrated by Air Force of PRC in China, and flight control is also supervised by Air Force of PRC; and the ATM in America is governed by government, it is an independent system. China has two systems of ATC, it is extremely important for us to coordinate the two systems at the same time in case to be safe. Additionally, the management structure of Chinese civil aviation is divided into three levels, the information system developed differently (web circumstances, hardware, and data standards are deviated), when developing SWIM the differences should be taken into consideration. Last but not the least, American and Europe all adopted web services to develop SWIM, but there still lies some room for improvement in operation efficiency. In terms of this, our SWIM developing teams should bring forth new ideas based on current mature technologies.

4 Conclusion

SWIM will provide ATM information sharing with flexible, safe and open information management architecture; it can address the isolation, repeated, inconsistent upgraded problems of current systems. Although China set up late in developing SWIM, the progress is fruitful in SWIM constructing. What's more, staying in contact with international advanced technologies will enable long-term growth of our civil aviation. In the future, China will still collaborates with USA and Europe in constructing SWIM, uses the mature experience to accelerate the informatization progress of Chinese civil aviation.

Keywords: Big Cities; Small-medium Cities; Bus Transit Network Design

Abstract. With the rapid development of the national economy, the construction of China's urban transportation is in the stage of rapid development. Both big cities and small-medium cities increasingly appear all kinds of issues such as traffic congestion. Priority to the development of public transport is the most effective way to solve the problem of urban traffic congestion, and urban bus transit network design is the first step in the planning of the public transport system, plays a vital role in the transportation system planning. Bus transit network generally consisted of rail transit, bus rapid transit and conventional bus in big cities, while it composed of conventional bus in small-medium cities. Therefore, this paper made research on the applicability of bus transit network design methods for different sized cities, analyzed the advantages and disadvantages of different methods, and explored a more excellent method for bus transit network design.

Introduction

With the development of economy, many cities in our country appeared the problem such as traffic congestion, traffic fairness and so on. The development of public transport is the most effective way to manage urban traffic congestion, through reasonable bus transit network design can take advantage of public transportation, improve bus service levels, facilitate urban trips, but also maximum ease road traffic pressure.

The early sixties of the last century, the main bus transit network design using qualitative methods, in general, it uses the formation that the authority of experts suggested forming line network layout, but the line program is rarely used quantitative analysis, it is likely to deviate from the actual situation. The late sixties to the early eighties of last century, bus transit network design based on the principle of combining related operations research and systems engineering, using the optimization of objective function lay line network. For example, in 1967, Lampkin [1] established a line network design model, which the comfort of passengers together with travel time as bus transit network service indicators. In 1968, Hirsch [2] tried to use fixed expenses to optimize bus network, the bus network optimization model has been designed as a fixed demand model. Since the late 1980 s, with the development of computer technology, heuristic algorithm was introduced to solve the bus transit optimization problem, such as artificial neural network and genetic algorithm. In 1998, Pattnaik [3] has proposed the use of genetic algorithm to design a bus transit network, the goal of the model is all bus passenger travel cost and operation cost minimum, generating circuit for selection first, and then optimized by genetic algorithm.

Starting from the bus transit network design development up to now, for the different size of the city's bus transit network approach has not been clear distinction. Public transport planning researchers have proposed all sorts of different method for the big cities characteristics, the bus transit network design in the big city is actual and applied. But the small-medium city's bus transit network is often in accordance with the big city's existing designed experience to implement, ignoring the small-medium city's road network is not mature, the proportion of bus travel is relatively low. It results problems that the bus transit attraction is inadequate and the utilization of bus transit network is not high, hindered the healthy development of the public transportation. As a result, depending on the city scale to divide the applicability of the different transit network design method, it plays a positive role in the development of urban public traffic. According to the different

traffic characteristics of the big cities and small-medium cities, the research that is suitable for different size of the city's bus transit network design method is very necessary.

The Division of Urban Size

At present, the theory of public transportation system planning has been preliminarily established, and gradually mature, so the distinctiveness of different scale of the city's public transportation system planning is very necessary. In this paper, in terms of the scale of urban development, road system, the size of the city has been divided.

"Green book of the small and medium-sized cities" promulgated in 2010 according to the present situation of China's urban population scale, put forward the new standard of city scale: The urban resident population below 1 million for the small-medium cities, more than 1 million for the big cities. The small-medium cities public transportation is composed of regular bus, public traffic in big cities usually consist of rail transit, bus rapid transit and conventional public. Small-medium city road network layout is a single chessboard, banded or radial, the general layout of road network in big cities by a mixture of a variety of forms, such as chessboard - ring - radiation hybrid and multicenter group, etc.

Either population size or road scale, the small-medium cities have different degrees of differences from the big cities. According to the above division of urban size, we can see that small-medium cities and big cities road traffic system differences mainly reflect in the following respects: Big cities road network system is relatively complete, forming a mature network system with expressway, arterial road, sub arterial road and branch, while small-medium cities arterial road network system is not formed or immature. Big cities road functional orientation is relatively clear, for example, the expressway plays a role of traffic rapid distribution, arterial road connects all major cities partitions, sub arterial road has both transport function and service function, the main function of the branch is service, while small cities road functional orientation is not clear.

Bus Transit Network Design Method for Small-medium Cities

Small-medium cities don’t pay attention to the problem of traffic planning in the early stages of urban development, compared with big cities, small-medium cities are relatively narrow, the arterial road network is not mature, traffic management condition is poor. Because residents travel distance is shorter, and bus transit design is not reasonable, leading the bus attraction is not enough, so it should start from the traffic characteristics and traffic demand of small-medium cities, using suitable for small-medium cities of bus transit network design method. The following summarizes several suitable for small-medium cities of bus transit network design method.

Manual Approach. Manual approach is a subjective experienced planning method at the early development stage of bus transit network design. Planners according to the line network planning and design principles or relevant specification of the bus transit planning manual listed, by virtue of their professional knowledge and technical experience to prepare bus transit network solutions. This method is suitable for small scale, simple road network in early urban development period, possesses the advantages of simple, convenient, low cost, but this kind of planning method is lack of scientific basis, the generated line network efficiency is not high.

System Analysis. System analysis is a bus transit network design method based on the evaluation. This method is based on the using of systems engineering and operations research relevant principles and methods, first preliminary design based on the experience of public transportation network planners, and then according to the passenger flow distribution theory and method to calculate the effect of each program line, and establish the evaluation model for comprehensive evaluation of bus transit network, if not satisfied with the evaluation results, we should adjust the bus transit network. This method is suitable for the complicated network, more lines of small-medium cities of recent or long-term strategic planning, with the advantages of systematic, simple, low cost, can be used for multi-objective optimization, suitable for comprehensive analysis, can objectively reaction of bus passenger flow demand. But it needs a large number of data, and manual participation more, less testing program.

Detailed Wiring Method [4]. Detailed wiring method namely "detailed layout, optimized network" method, it means of all the alternative routes, select direct passenger volume as the main target, find out the optimal bus lines, and according to the shortest route layout.

By the direct passengers to maximization as the objective function:

$$MaxS = \sum_{i=1}^{n} \sum_{j=1}^{n} z_{ij} x_{ij} \quad . \tag{1}$$

Among them: z_{ij} -- the line ij direct passenger volume;

x_{ij} -- 0-1variables, if the starting point i and end point j pairs, then $x_{ij} = 1$, otherwise $x_{ij} = 0$.

The method is based on the data support, in full consideration of the district bus OD traffic volume, correct the length of the line and non-linear coefficient, not only the model is put forward, but also easier to get the optimized bus routes. The idea is simple, intuitive, and practical, it is commonly used as a small-medium cities bus transit network design method. But it lacks reasonable feedback after this network, requires adjustment process repeated, and rework is too heavy.

Improved Detailed Wiring Method [5]. Since detailed wiring method only to direct passengers volume maximization as the goal, may ignore the influence of several other constraints, so with the idea that the main objective optimization first, and then the secondary objective optimization to make the improvement of detailed wiring method, to make up for the problem of insufficient for other constraint optimization. It proposed the line optimal coefficient Q, which is the minimum value of the sum of the coefficient on each section of alternate routes, find the minimum value of the sum of the coefficient on each road can determine the line with the optimal coefficient Q, then we can find the corresponding the biggest direct passenger volume's optimal routes.

The optimal coefficient Q calculation formula is as follows:

$$\begin{aligned} Q &= \min \sum_{O}^{D} Q_i \\ Q_i &= A_i + B_{ij} \\ A_i &= (L_i / L_0) \bullet 100 \\ A_0 &= A_{\max} - A_{\min} \\ B_{ij} &= A_{\min} + \lambda_j A_0 \end{aligned} \quad . \tag{2}$$

Among them: A_i--road length factor of section i;

B_{ij} --road grade value of section i;

λ_j -- weighting factor of road grade;

L_i --the length of section i;

L_0 -- the total length of all sections.

This method on the basis of the detailed wiring method, the original layout on the shortest path upgraded to layout in accordance with the minimum value of the sum of the coefficient on each section, more able to adapt the characteristics of small-medium cities bus transit network design. But the influence factors of sections coefficient use road length factor and road grade value, if they can make good choice to bus transit network design remains to be further research.

Flexible Bus Transit Network Design Method [6]. The flexible bus is a kind of dynamic bus service, bus lines don't have fixed sites and fixed lines, each bus line transports passengers within a particular service area, the vehicle's trajectory is related to the passengers trip distribution, according to the requirements of passengers pick up passengers. The flexible bus operating costs and user costs into the cost per unit time get the objective function is as follows:

$$\min Z = \lambda_Q Q + \lambda_M M + T + \delta e_T \quad . \tag{3}$$

Among them: Q --the total running distance of all vehicles unit hour;

M --all vehicles total operating time;

T --the time passengers in car;

e_T --transfer passengers heart punishment costs;

Flexible bus transit network design method can not only provide high quality service level for passengers, but also save the cost of operators, but the implementation of this method needs corresponding road system, vehicle positioning system, dispatching system and GIS to support and cooperation, and needs practice to verify analysis.

Bus Transit Network Design Method for Big Cities

Big cities have many features include frequent social economic activities, large population, large area, urban function zoning obvious and so on. With the great changes in urban social and economic structure, residents travel numbers grow in multiply, in order to solve the contradiction between bus supply and passengers travel demand, it provides big cities bus transit network design method as follows:

Interactive Auxiliary System Analysis Method Based on Computer. With the development of computer technology, geographic information system and the database management system, bus transit network design can directly do the interactive bus transit network optimization and evaluation with users by the help of computer arithmetic functions. Available computer can quickly process a large number of OD information and network information, and can output a variety of intuitive graphics, planners modification is also more convenient. But the cost is high, and it tends to improve the existing network, and is limited to the computer's capacity and processing power.

Mathematical Optimization Method [7]. Mathematical optimization method simplifies supply and demand relationship between bus transit network structure and passengers demand, establish a mathematical model to determine the optimal bus transit network solution. Issue of bus transit network design is a complicated multi-objective combinatorial optimization problem, its purpose is to make the balance of total travel cost at least, total operating cost minimum and most transport and traffic, making the maximal profit of the system. The objective function is as follows:

$$Max\varphi = \lambda_1(-W) + \lambda_2(-C) + \lambda_3 P \ . \tag{4}$$

Among them: W --travelers travel costs, including bus fares and travel time cost;

C --bus operating costs;

P --bus system fare revenue, equivalent to the transport of bus system;

λ_i --the weight factor of each objective function, and $\lambda_1 + \lambda_2 + \lambda_3 = 1$.

This method is a scientific and systematic method, using heuristic algorithm can get the optimal solution, but costs a lot, all candidates need to analyze, solving is more complex.

Hierarchical Planning Method [8]. Hierarchical planning method divides urban bus transit network into three levels of bus trunk, bus sub trunk, bus branch. First determine bus trunk network with the shortest travel time as the goal, and then determine bus sub trunk network with the goal of maximizing the direct passenger flow density, finally determine bus branch network with the goal of maximizing the line network coverage.

Bus trunk objective function:

$$\min T = \sum_i \sum_j Q_{ij} \bullet T_{ij} \ . \tag{5}$$

Among them: T -- line network total running time;

Q_{ij} -- OD volume from point i to point j;

Bus sub trunk objective function:

$$\max D = \max \sum D_{ij} = \max \sum \frac{\sum_{\forall i, j \in ij} q_{ij}}{l_{ij}} \ . \tag{6}$$

Among them: q_{ij} -- OD volume from the starting point i to the end of j of line ij;

l_{ij} -- the total length of line ij.

Bus branch objective function:

$$\max C = \max \sum C_{ij} \ . \tag{7}$$

Among them: C_{ij} -- the number of bus stops and travel centralized endpoints in line ij .

This method is simple, intuitive and feasible, it is suitable for big cities bus transit network design, but lack of reasonable feedback after forming network, needs to repeat the adjustment process, duplication of effort is more.

Rail Transit Feeder Bus Transit Network Design Method [9]. With the dominance of rail traffic in the big cities are becoming more evident, laid feeder bus lines to achieve efficient convergence with rail transportation has become research focus in big cities. This paper introduces a kind of feeder bus transit network design method with the goal of maximizing the efficiency of feeder lines, and discrete processing, building the objective function as follows:

$$\max E_i^F = \frac{\sum_{j=1}^{J} \left(q_{ij}^{FR} + q_{ji}^{RF} \right) \cdot l_{ij}^R}{\sum_{y=0}^{m} \sum_{x=0}^{n-1} A_{xy}^X w + \sum_{y=0}^{m-1} \sum_{x=0}^{n} A_{xy}^Y w} \ . \tag{8}$$

Among them: l_{ij}^R --the length from the track station i to j ;

q_{ij}^{FR} --passenger traffic volume that pick off the feeder line, from the track station i get on the car to the track station j ;

q_{ji}^{RF} -- passenger traffic volume that from the track station j get on the car to the track station i , and then take the feeder bus to destination;

Bus Rapid Transit Design Method [10]. In a variety of public transport vehicles, due to regular bus passenger traffic capacity is small, speed is slow, rail transport has large capacity, high speed, high service levels, but large investment, long construction period, slow return on investment, so there is bus rapid transit in big cities.

BRT mainly act as a “point to point” of the mass rapid transport tasks, bus lines should be laid in order to reach the largest amount of passengers as the goal. If the planning pivot point has n, the mathematical model is as follows:

$$\begin{aligned} &\max S = \sum_{i=1}^{n} \sum_{j=1}^{n} Z_{ij} \cdot X_{ij} \\ &\sum_{i=1}^{n} X_{ij} = 1 \qquad i = 1, 2, \cdots, n \\ &\sum_{j=1}^{n} X_{ij} = 1 \qquad j = 1, 2, \cdots, n \end{aligned} \ . \tag{9}$$

Among them: Z_{ij} -- when the starting point i and the end of j pairs, the amount of direct passengers the line can transport;

X_{ij} -- 0-1variables, if the starting point i and the end of j pairs1, then X_{ij} =1, otherwise X_{ij} =0.

Conclusion

Public transportation plays an important role in urban traffic network, for the convenience of the residents travel and ease congestion has an irreplaceable role. According to bus transit network design methods for different sized cities summarized above, bus transit network design methods should distinguish between big cities and small-medium cities will more conducive to the development of different sized cities public transportation, and find out a suitable bus transit network design method for different sized city.

Small-medium cities bus transit network design method can use the improved detailed wiring method, with the main objective of maximizing the direct passenger quantity, and then according to

the concrete practice of the city, with one or more other factors as the secondary goal for bus transit network design.

For passenger traffic in big cities should with rail transit as skeleton, bus rapid transit for assistance, regular bus as the main body, with full attention to rail and bus lines hubs planning, and make it progressively into a network to meet the travel needs of big cities. It should use the hierarchical planning method for different levels of bus transit with different objective functions in order to protect the applicability for various levels of bus transit network design method, combined with constraint conditions to heuristic solving, draw bus transit network layout solution.

Keywords: Ontology, Agricultural information, Management, Retrieval

Abstract. In order to improve the efficiency of agricultural information retrieval and provide the effect methods for the information retrieval of agricultural, the intelligent searching technology of agricultural information based on ontology is proposed. The paper firstly introduces the concept of ontology, analyzes the characters of agricultural knowledge, and constructs the related agricultural knowledge ontology and knowledge base, implementing the intelligent searching of the agricultural information. The results indicate that the research on agricultural ontology can contribute to organization and searching of agricultural scientific knowledge and provide methods for information organization and searching of agricultural knowledge.

Introduction

To search effective agricultural information from large and fast changing network requires that the user has to navigate the relevant information server without the help of tool, the large number of unnecessary information is surfing on the network, which not only increases the burden on the server, occupies the bandwidth of network and affects the speed of the network, but also increases data flow of network user[1], which enables users to pay unnecessary network cost and valuable time. The research and development of key technology on agricultural knowledge and semantic retrieve will provide knowledge retrieval technology based on agriculture domain ontology, and the single platform is used to access a variety of knowledge resources and to carry out the organization, mining[2], the retrieval and expression of agriculture, agricultural knowledge service which belongs to one or multiple is used to be made, which can greatly improve the accuracy and reliability of agricultural information retrieval.

Related Research

Agricultural Knowledge. Agriculture knowledge includes explicit knowledge and tacit knowledge, the explicit knowledge is easy to be saved and distributed by the information technology, and the tacit knowledge usually are the experience, skills and sixth sense of intuition, and sometimes only means that are not conveyed in words, which are dominant outsider, and which requires people make the formal code, the information technology is used to reach external storage and transmission, sharing and widely application of agricultural, the agricultural knowledge are different from the agricultural information, information and knowledge are interrelated and interdependent, but are very distinct[2].

Semantic Retrieval. The semantic retrieval of agricultural knowledge is not only single point urgent need of agricultural information service, but further is the premise and foundation of distributed knowledge grid environment semantic retrieval. Semantic retrieval of agricultural knowledge can not simply rely on semantic search technology literature resources, rapidly growing network of information resources and vast spatial information resource, meanwhile are also important information resources for semantic retrieval. In order to solve the current problems of information retrieval, the searching technology is more effective tool that is firstly applied to the network information searching. But there are some defects such as poor real-time information, searching technology in the database can not be changed with the network of dynamic documents, which is unable to provide timely updated information for the users, information seekers are poor and can not retrieve the corresponding areas of information according to the requirements of users,

leading to emergence of large number of irrelevant information, and frequently using searching technology every day for millions of users with services, even if such searching technology that uses high-performance server hardware systems is also difficult to provide such a range of rapid response[3].

Agricultural Ontology. Ontology is defined as the system description of objective world, and artificial intelligent regards ontology as basic terms and relation which made vocabulary of related fields, and the definition of extension of the rules that use relationships and these terms is made. As ontology is regarded as conceptual model tools which descript knowledge of information system in the semantic and knowledge level, since the introduction of domestic is made ,then foreign researchers pay great concern on it, and has been widely used in many areas of computer, which has good concept hierarchy structure and support of logical reasoning, and thus the ontology is used in semantic retrieve of information retrieve, it is intelligent search which is based on the conceptual understanding level and thinking searching[4]. The goal of ontology is to capture the relevant knowledge in the field, providing common understanding of knowledge of this area, determining the agreed-upon terms of areas and gives these words and the clear definition of terms of the interrelationship from different levels of formal model, through the relationship of concept the semantics of concept is described.

Application of Agricultural Ontology

Establishment of Agricultural Ontology. The ontology provides a set of terms and concepts to describe some field of agricultural information, the object library uses the ontology to express these terms in the field of facts and knowledge. The establishment of ontology knowledge base is to collect the information source data, with reference to the established ontology metadata model, all kinds of heterogeneous will be unified into a unified document format, and make restructuring and integration, which can solve the problems of heterogeneous nature.

Establishment of Distributed Data Collection Model. The establishment of universal applicability of the large multi-level distributed data acquisition model can help retrieval system to find data, which is one of the key of this study. In view of the proposes of data collection, providing protection for the source of information of the system can be effectively used for further information after the semantic reasoning and retrieval of information request.The issue to be resolved is to establish the page document vector space model and extract related topics from agricultural knowledge based on the relationship between learning algorithm model.

Document Classification. The ontology object library is a dynamic process, in order to keep pace with the ontology library and information resources, the system retrieves the introduction of intelligent agents in adaptive learning, when the retrieval agent in system service is small, the statistical user makes preference ontology library content, access user interest trends, and then take the initiative to build a searching query and submit to the search agent, then the searching agent can access the information resources, get new documents of related fields [5].

Establishment of Retrieval Reasoning Model. Reasoning model is the key of intelligent retrieval of knowledge, during the process of knowledge of agricultural products of intelligent searching, the retrieval system can obtain the access to the request from the user interface, then converters the request into the specified format, match data sets of requirement from the meta-database, further refer to enquiry goals and results is returned to users. The enquiries converter is achieved by calculating the similarity. This paper is to adopt the S-Match algorithm of calculating the similarity which includes the structure of shallow, middle and deep mapping mode. S-Match algorithm requires the input of two concepts c and c ', the concept of mapping patterns, combined mode. The output is the 'semantic similar to the comprehensive level of the concept c and c. Optional models includes the concept of mapping of shallow, middle and deep. Mapping of shallow-level language calculated only similarity, middle-class language, including mapping and structural similarity level, deep mapping addition, examples of calculation of similarity and the similarity of reasoning. Model portfolio, including the right to re-mix and Sigmoid function. If you

choose the former, you need to weight the array, if the latter is chosen, the requirements of the slope parameters[6-7].

Simulation Results and Discussion

Three Levels of System. The front of web browser is responsible for the display of classification tree and classification navigation information, the input, selection of searching criteria and performance of data enquiry results; The application of web server encapsulates all business logic, including the establishment of dynamic connection with database, enquiry and submission of sql, xql, parsing of xml, the traversal of dom tree and the expression which apply xslt and so on. Two database management systems of background database contain software tamino and MySQL. Tamino database stores category navigation information; And MySQL database stores information of forty thousand literature data. In fact forty thousand pieces of data information can be stored in Tamino database, so that navigation information and data information can be stored in database system, and simplify the complexity of development.

Simulation. The comparison of intelligent retrieval methods and the conventional methods are shown in Table 1:

TABLE I. THE COMPARISON

Traditional methods		Improved methods	
Accuracy	Recall	Accuracy	Recall
78	79	88	89
87	86	90	92
88	87	96	90
89	84	92	94
84	89	91	93
82	85	90	91
83	80	93	90
81	83	92	93
80	82	93	94
83	87	94	95
82	88	91	96
78	86	98	98
89	88	98	98

Discussion. It can seen from the simulation that the recall rate is higher than the conventional retrieval under the same conditions, and the precision rate of is more, which is also significantly better than the conventional retrieval precision. In short, the system fully considers the thinking way of people, reflects the level of structure in the organization of agricultural information, so the efficiency of user clicks is improved, and the relationship between the concepts which are described by ontology is applied to the retrieval of information, especially while the user is not certain for queries target, it can better reflect the intelligence analysis of user requirement and retrieval results effect.

Conclusion

This paper describes agricultural information retrieval model based on ontology, and the architecture, function and work flow are made. The research on agricultural ontology construction technology will contribute to the ontology establishment of different domains in agricultural information, and gradually build larger domain agricultural ontology which can develop from the senior or junior ontology to the heavy weight ontology, and lay the foundation for information resources of the network organization and construction of semantic web, making the organization of agricultural information resources, so the research on the ontology has general scientific significance and practical value.

Keywords: bond; term structure of interest rate; yield curve; structural change

Abstract. Using the price data of bonds' transactions during June 2013, the discounting function is fitted by non-uniform cubic B-Splines and yield curves are modeled. Models' single parametric test and total test are both significant. Furthermore, the structural change's test shows that there is no significant structural change between adjacent transaction days, which means that the bonds' market is relatively steady during June 2013.

Introduction

In June 2013, Money-Shortage-Event broke out in China's financial market. From May, the interest rates had been soaring, on 19th June, Shanghai Interbank Offered Rate(Shibor) soared 578.4 basis points, reached 13.4440 points. After inter-bank interest rates hitted record, the interest rates dropped sharply almost 500 basis points on June 21 [1,2].Interest rate's term structure implied by bond market is functional relationship between risk-free rate of interest and duration. Interest rate's term structure plays a key role in economic and financial analysis and it is an important index for the research and the formulation of monetary policy[3].

Before the event, does the bond market predict the market's volatility? During the event, does the bond market fluctuate with the event? After the event, is the bond market affected by markets significantly? In this paper, with the Book-entry treasury bonds transaction price data throughout total, daily yield curves are constructed by non-uniform B-spline fitting. And structural changes of models between the adjacent transaction days are tested.

Model's Theoretical Analysis

Interest rate's term structure is illustrated by zero-coupon yield curve. Many spline models on the interest rate's term structure, such as polynomial spline model, exponential spline model, B-spline model are utilized[3,4,5,6]. In this paper, with the widely used non-uniform cubic B-spline, discounting function is fitted.

Note discount function as

$$\delta(t), \qquad t \in [0,T].$$

Where T is the maximum value of residual maturities for all the bonds. To the l*th* bond, whose cash paid at time t_j $(j=1,...,N_l)$ is $C_l(t_j)$, then the bond price P_l is

$$P_l = \sum_{j=0}^{N_l} C_l(t_j)\delta(t_j) \qquad (1)$$

where $l=1,...,M$. M is the number of bonds. Make the discounting function expressed in a linear combination of B-spline basis functions

$$\delta(t) = \sum_{i=0}^{n-k-1} a_i B_i^k(t_j), \quad t \in [t_k, t_{n-k}]. \qquad (2)$$

Where $B_i^k(t)$ is the i th basis function of k-degree B-spline on a given interval of knot[7], $n+1$ is the number of knots, and a_i is parameters. Let

$$knots = \{t_0, t_1, t_{2,}, ..., t_n\},\ \ n \geq k.\quad t_i \leq t_{i+1},\ \ i = 0, ..., n-1.$$

From（1）and（2), we can obtain

$$P_l = \sum_{i=0}^{n-k+1} a_i (\sum_{j=0}^{N_l} B_i^k(t_j) C_l(t_j)).$$

Denoted by:

$$\mathbf{P} = (P_1, P_2, ..., P_M)^T,\quad \boldsymbol{\alpha} = (a_1, a_2, ..., a_{n\text{-}k+1})^T, \mathbf{X} = (x_{l,i}),$$

$$where\ x_{l,i} = \sum_{j=0}^{N_l} B_i^k(t_j) C_l(t_j),\ l = 1, ..., M.\ i = 0, ..., n-k+1.$$

Thus, the model is

$$\mathbf{P} = \mathbf{X}\boldsymbol{\alpha} + \boldsymbol{\varepsilon}. \qquad (3)$$

Where $\boldsymbol{\varepsilon}$ is the random disturbance assumed to satisfy with hypotheses of classical linear regression model. Thus by OLS regression, we have :

$$\boldsymbol{\alpha} = (\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T\mathbf{P}.$$

Then the zero-coupon yield curve is

$$r(t) = -\frac{\ln \delta(t)}{t}. \qquad (4)$$

Model's Empirical Study

(1) The selection of sample data

Transacttion price data from Shanghai Stock Exchange in June 2013 is used, and the bonds of zero transaction amount and floating rate, as well as issue price is not equal to 100, are eliminated. The sample size of each transaction day is shown in Table 1.

(2) The selection of knots in B spline basis function

The selection of knots number follows the principle of Ruppert et.(2003,Chapter 5) [8]. In order to choose internal knots reasonably, we select the knot interval which satisfies with the requirement that the number of matured bonds in each knot interval is almost the same. Finally, with the additional knots ,the determined knot vector is: $knots = \{-3, -2, 0, 0, 3, 8, 12, 12, 13, 14\}$.

Therefore, $k = 3, n = 10$. The number of spline segments is 6 and the defined interval of fitting discounting function is [0,12].

(3) The fitting results of models

In the 17 fitting models, by the good flexibility of B-spline fitting, the single parameter test in each model is highly significant. Because of the coefficients are too much(17*6=102), we just show degree of freedom and F value in the F test of every model in Table 1 rather than the *t* values and *p* values of each parameter. Fitting yield curves are showed in Figure 1 and we also calculated the values of 17 fitting yield curve in 3, 5 and 10 years, as shown in Table 2.

(4)Structural change test in models

In order to test whether there is a structural change between adjacent transaction day in the model, structural change for *i*th model and (*i*+1)th *m*odel are tested.

Parameter vectors for *i*th model and (*i*+1)th *m*odel are denoted by $\boldsymbol{\alpha}_i, \boldsymbol{\alpha}_{i+1}$ and the hypothesis of test is

$$H_0 : \boldsymbol{\alpha}_i = \boldsymbol{\alpha}_{i+1} \quad , \quad H_1 : \boldsymbol{\alpha}_i \neq \boldsymbol{\alpha}_{i+1} \ .$$

Test statistics is

$$F = \frac{(RSS_{\mathrm{T}}\text{-}RSS_i\text{-}RSS_{i+1}) / k}{(RSS_i + RSS_{i+1}) / (T-2k)} \sim F(k, T-2k)$$

Where RSS_i, RSS_{i+1} represents residual sum of squares of *i*th model and (i+1)th model, RSS_{T}represents the residual sum of squares of model based on the total data from both models. k, T represent the number of parameters in regression model and the sum of sample size of *i*th model and(*i*+1)th model[13]. Testing results are shown in Table 3.

Table 3 Structural change test of models between adjacent transaction days in June 2013

Tested Model	1/2	2/3	3/4	4/5	5/6	6/7	7/8	8/9	9/10
Degree of Freedom	(6, 29)	(6, 28)	(6, 24)	(6, 21)	(6, 24)	(6, 31)	(6, 31)	(6, 28)	(6, 29)
F value	0.80	0.02	0.39	0.89	0.69	1.02	0.28	0.06	0.08
Tested Model	10/11	11/12	12/13	13/14	14/15	15/16	16/17		
Degree of Freedom	(6, 29)	(6, 27)	(6, 26)	(6, 30)	(6, 24)	(6, 30)	(6, 16)		
F value	1.33	1.60	2.19	1.90	1.64	1.62	1.02		

Economical Analysis of Model

According to the results of 17 models, 17 yield curves are smooth and almost monotonically increasing, that is consistent with the liquidity-preferred-hypothesis. As Table 3, 16 test results are not significant under significance level of 0.01, hence we cannot reject the null hypothesis, which means that there is no sufficient evidence to support that the term structure between adjacent transaction days changed structurally during June 2013. Two factors may contribute to the stability. Firstly, bond market regards that volatility of interest rate is one kind of short-term behavior. Secondly, separation between bond market and inter-bank market in China leads to ineffective transmit mechanism between the two markets.

On the other hand, from the F values in table 3 and the date of models in table 1, we find that before June 19, F value is small, but from June 19 to 20, F value increases up to 1.33, which indicates that bondmarket is affected by the changes of the inter-bank market's interest rates. Especially from June 21 to 24, F value reaches a maximum value 2.19 in this month which indicates that the impact were accumulated during the weekend and released on the next Monday.

Concluded, although China's bond market is affected by the inter-bank market during the Money-Shortage-Event, the yield is changing gradually but not suddenly. Maybe two reasons explain that phenomena, one is the bonds' market is confident in the stability of the risk-free interest rate, the other is the fact that transmitting channel between the inter-bank market and the bond market is not completely open in China.
